Package ‘animation’

December 11, 2018

Type Package

Title A Gallery of Animations in Statistics and Utilities to Create Animations

Version 2.6

Description Provides functions for animations in statistics, covering topics in probability theory, mathematical statistics, multivariate statistics, non-parametric statistics, sampling survey, linear models, time series, computational statistics, data mining and machine learning. These functions may be helpful in teaching statistics and data analysis. Also provided in this package are a series of functions to save animations to various formats, e.g. Flash, 'GIF', HTML pages, 'PDF' and videos. 'PDF' animations can be inserted into 'Sweave' / 'knitr' easily.

SystemRequirements ImageMagick (http://imagemagick.org) or GraphicsMagick (http://www.graphicsmagick.org) or LyX (http://www.lyx.org) for saveGIF(); (PDF)LaTeX for saveLatex(); SWF Tools (http://swftools.org) for saveSWF(); FFmpeg (http://ffmpeg.org) or avconv (https://libav.org/avconv.html) for saveVideo()

Depends R (>= 2.14.0)

Imports magick

Suggests MASS, class, testit

License GPL

Description

This package contains a variety functions for animations in statistics which could probably aid in teaching statistics and data analysis; it also has several utilities to export R animations to other formats.

Details

This package mainly makes use of HTML & JavaScript and R windows graphics devices (such as \texttt{x11}) to demonstrate animations in statistics; other kinds of output such as Flash (SWF) or GIF animations or PDF animations are also available if required software packages have been installed. See below for details on each type of animation.

On-screen Animations

It’s natural and easy to create an animation in R using the windows graphics device, e.g. in \texttt{x11()} or \texttt{windows()}. A basic scheme is like the Example 1 (see below).

On-screen animations do not depend on any third-party software, but the rendering speed of the windows graphics devices is often slow, so the animation might not be smooth (especially under Linux and Mac OS).

HTML Pages

The generation of HTML animation pages does not rely on any third-party software either, and we only need a web browser to watch the animation. See \texttt{saveHTML}.

The HTML interface is just like a movie player – it comes with a series of buttons to control the animation (play, stop, next, previous, ...).
This HTML approach is flexible enough to be used even in Rweb, which means we do not really have to install R to create animations! There is a demo in system.file('misc', 'Rweb', 'demo.html', package = 'animation'). We can use `saveHTML` to create animations directly in Rweb; this can be helpful when we do not have R or cannot install R.

**GIF Animations**

If ImageMagick or GraphicsMagick has been installed, we can use `im.convert` or `gm.convert` to create a GIF animation (combining several R plots together), or use `saveGIF` to create a GIF animation from an R code chunk.

**Flash Animations**

If SWF Tools has been installed, we can use `saveSWF` to create a Flash animation (again, combining R plots).

**PDF Animations**

If LaTeX is present in the system, we can use `saveLatex` to insert animations into a PDF document and watch the animation using the Adobe reader.

The animation is created by the LaTeX package `animate`.

**Video**

The function `saveVideo` can use FFmpeg to convert images to various video formats (e.g. `'mp4'`, `'avi'` and `'wmv'`, etc).

**Note**

Bug reports and feature requests can be sent to https://github.com/yihui/animation/issues.

(NB: some functions mentioned in the above article have been slightly modified; see the help pages for the up-to-date usage.)

ani.options

See Also

saveHTML, saveGIF, saveSWF, saveVideo, saveLatex

ani.options

Set or query animation options

Description

There are various parameters that control the behaviour of the animation, such as time interval, maximum number of animation frames, height and width, etc.

Usage

ani.options(...)

Arguments

... arguments in tag = value form, or a list of tagged values. The tags usually come from the animation parameters described below, but they are not restricted to these tags (any tag can be used; this is similar to options).

Value

ani.options() returns a list containing the options: when parameters are set, their former values are returned in an invisible named list. Such a list can be passed as an argument to ani.options to restore the parameter values.

ani.options('tag') returns the value of the option 'tag'.

ani.options(c('tag1', 'tag2')) or ani.options('tag1', 'tag2') returns a list containing the corresponding options.

Animation options

The supported animation parameters:

interval a positive number to set the time interval of the animation (unit in seconds); default to be 1.

nmax maximum number of steps in a loop (e.g. iterations) to create animation frames. Note: the actual number of frames can be less than this number, depending on specific animations. Default to be 50.

ani.width, ani.height width and height of image frames (unit in px); see graphics devices like png, jpeg, ...; default to be 480. NB: for different graphics devices, the units of these values might be different, e.g. PDF devices usually use inches, whereas bitmap devices often use pixels.

ani.res The nominal resolution in ppi which will be recorded in the bitmap file, if a positive integer. Also used for units other than the default, and to convert points to pixels.; see graphics devices like png, jpeg.
ani.options

imgnfmt Customizing image number format in saveHTML, saveGIF, saveLatex and saveVideo, saveSWF is not included, it allows user to define the C-style string format for output image.

imgdir character: the name of the directory (a relative path) for images when creating HTML animation pages; default to be ‘images’.

htmlfile character: name of the target HTML main file (without path name; basename only; default to be ‘index.html’)

ani.dev a function or a function name: the graphics device; e.g. (png, pdf, ...); default to be ‘png’

ani.type character: image format for animation frames, e.g. png, jpeg, ...; default to be ‘png’; this will be used as the file extension of images, so don’t forget to change this option as well when you changed the option ani.dev

title, description character: the title and description of the animation in the HTML page created by saveHTML

verbose logical or character: if TRUE, write a footer part in the HTML page containing detailed technical information; if given a character string, it will be used as the footer message; in other cases, the footer of the page will be blank.

loop logical or numeric: Number of times the GIF animation is to cycle through the image sequence before stopping. By default, this is set to zero or boolean value TRUE (infinite loop).

autobrowse logical: whether auto-browse the animation page immediately after it is created? (default to be interactive())

autoplay logical: whether to autoplay the animation when the HTML page is loaded (default to be TRUE); only applicable to saveHTML

use.dev whether to use the graphics device specified in ani.options('ani.dev') (default to be TRUE); if FALSE, we need to generate image files by our own approaches in the expression expr (see functions saveHTML, saveGIF, saveLatex and saveSWF); this can be useful when the output cannot be captured by standard R graphics devices – a typical example is the rgl graphics (we can use rgl.snapshot to capture rgl graphics to png files, or rgl.postscript to save plots as postscript/pdf; see demo('rgl_animation') or demo('use_cairo') for examples or the last example below). Note, however, we do not really have to create the images using R graphics devices – see demo('flowers') on how to download images from the Internet and create an HTML animation page!

Hidden options

There are a couple of “hidden” options which are designed to facilitate the usage of some functions but are not initialized like the above options when the package is loaded, including:

convert this option will be checked first when calling im.convert (or saveGIF) to see if it contains the path to ‘convert.exe’; we can specify it beforehand to save the efforts in searching for ‘convert.exe’ in ImageMagick under Windows. For example, ani.options(convert = 'c:/program files/imagemagick/convert.exe'); note this option also works for Mac and Linux (see help(im.convert))

swftools this can help saveSWF save the efforts of searching for the software package “SWF Tools” under Windows; e.g. we can specify ani.options(swftools = 'c:/program files/swftools') in advance
ani.options

**img.fmt** the value of this option can be used to determine the image filename format when we want to use custom graphics devices to record images, e.g. in `saveLatex`, if `ani.options('use.dev') == FALSE`, then `ani.options('img.fmt')` will be a string like 'path/to/output/img.name%d.png', so we can use it to generate file names in the argument `expr`; see demo(`'rgl_animation'`) for example or the last example below.

**qpdf** the path of the program qpdf, e.g. `ani.options(qpdf = 'C:/Software/qpdf/bin/qpdf.exe');` qpdf is mainly used to compress PDF files in this package, and it is a smaller tool than pdftk. It is recommended over pdftk especially under Linux, because tests show that pdftk does not work well under Linux in compressing PDF files, while qpdf is much better.

**pdftk** the path of the program pdftk, e.g. `ani.options(pdftk = 'C:/Software/pdftk.exe')` or `ani.options(pdftk = '/home/john/bin/pdftk');` pdftk will be used to compress the PDF graphics output in the function `pdftk`; compression will not be tried if this options is NULL. This option will only affect `saveGIF, saveLatex` and `saveSWF` when `ani.options('ani.type')` is 'pdf'.

**ffmpeg** the path of the program ffmpeg, e.g. `ani.options(ffmpeg = 'C:/Software/ffmpeg/bin/ffmpeg.exe');` FFmpeg is used to convert a sequence of images to a video. See `saveVideo`.

**Note**

Please note that `nmax` is not always equal to the number of animation frames. Sometimes there is more than one frame recorded in a single step of a loop, for instance, there are 2 frames generated in each step of `kmeans ani`, and 4 frames in `knn ani`, etc; whereas for `newton method`, the number of animation frames is not definite, because there are other criteria to break the loop.

This function can be used for almost all the animation functions such as `brownian motion, boot iid, buffon needle, cv ani, flip coin, kmeans ani, knn ani`, etc. Most of the options here will affect the behaviour of animations of the formats HTML, GIF, SWF and PDF; on-screen animations are only affected by `interval` and `nmax`.

`http://qpdf.sourceforge.net/`

`http://www.pdflabs.com/docs/pdftk-man-page/`
ani.pause

Pause for a while and flush the current graphical device

Description

If this function is called in an interactive graphics device, it will pause for a time interval (by default specified in `ani.options('interval')`) and flush the current device; otherwise it will do nothing.

Usage

```r
ani.pause(interval = ani.options("interval"))
```

Arguments

- `interval`: a time interval to pause (in seconds)

Value

Invisible `NULL`.

Author(s)

Yihui Xie

See Also

`dev.interactive`, `Sys.sleep`, `dev.flush`

Examples

```r
## pause for 2 seconds
oopt = ani.options(interval = 2)

for (i in 1:5) {
  plot(runif(10), ylim = c(0, 1))
  ani.pause()
}

ani.options(oopt)

## see demo('Xmas2', package = 'animation') for another example
```
Description

These two functions use `recordPlot` and `replayPlot` to record image frames and replay the animation respectively.

Replay the animation

Usage

```r
ani.record(reset = FALSE, replay.cur = FALSE)
```

```r
ani.replay(list)
```

Arguments

- `reset` if TRUE, the recording list will be cleared, otherwise new plots will be appended to the existing list of recorded plots
- `replay.cur` whether to replay the current plot (we can set both `reset` and `replay.cur` to TRUE so that low-level plotting changes can be captured by off-screen graphics devices without storing all the plots in memory; see Note)
- `list` a list of recorded plots; if missing, the recorded plots by `ani.record` will be used

Details

One difficulty in capturing images in R (base graphics) is that the off-screen graphics devices cannot capture low-level plotting commands as new image files – only high-level plotting commands can produce new image files; `ani.record` uses `recordPlot` to record the plots when any changes are made on the current plot. For a graphical device to be recordable, you have to call `dev.control('enable')` before plotting.

`ani.replay` can replay the recorded plots as an animation. Moreover, we can convert the recorded plots to other formats too, e.g. use `saveHTML` and friends.

The recorded plots are stored as a list in `.ani.env$.images, which is the default value to be passed to `ani.replay`; `.ani.env` is an invisible `environment` created when this package is loaded, and it will be used to store some commonly used objects such as animation options (`ani.options`).

Value

Invisible NULL.
Note

Although we can record changes made by low-level plotting commands using `ani.record`, there is a price to pay – we need memory to store the recorded plots, which are usually very large when the plots are complicated (e.g. we draw millions of points or polygons in a single plot). However, we can set `replay.cur` to force R to produce a new copy of the current plot, which will be automatically recorded by off-screen graphics devices as new image files. This method has a limitation: we must open a screen device to assist R to record the plots. See the last example below. We must be very careful that no other graphics devices are opened before we use this function.

If we use base graphics, we should bear in mind that the background colors of the plots might be transparent, which could lead to problems in HTML animation pages when we use the `png` device (see the examples below).

**Author(s)**

Yihui Xie

**References**

Examples at [https://yihui.name/animation/example/ani-record/](https://yihui.name/animation/example/ani-record/)

**See Also**

`recordPlot` and `replayPlot`: `ani.pause`

**Examples**

```r
library(animation)

n = 20
x = sort(rnorm(n))
y = rnorm(n)
## set up an empty frame, then add points one by one
par(bg = "white")  # ensure the background color is white
plot(x, y, type = "n")

ani.record(reset = TRUE)  # clear history before recording

for (i in 1:n) {
  points(x[i], y[i], pch = 19, cex = 2)
  ani.record()  # record the current frame
}

## now we can replay it, with an appropriate pause between frames
oopts = ani.options(interval = 0.5)
ani.replay()

## or export the animation to an HTML page
saveHTML(ani.replay(), img.name = "record_plot")

## record plots and replay immediately
saveHTML(
```
Deviation and control HB can enable recording, allowing for the background color to be white.

```r
plot(x, y, type = "n")
for (i in 1:n) {
  points(x[i], y[i], pch = 19, cex = 2)
  ani.record(reset = TRUE, replay.cur = TRUE) # record the current frame
}
}
ani.options(oopts)
```

---

**bisection.method**

Demonstration of the Bisection Method for root-finding on an interval

---

**Description**

This is a visual demonstration of finding the root of an equation $f(x) = 0$ on an interval using the Bisection Method.

**Usage**

```r
bisection.method(FUN = function(x) x^2 - 4, rg = c(-1, 10), tol = 0.001,
  interact = FALSE, main, xlab, ylab, ...)
```

**Arguments**

- `FUN` the function in the equation to solve (univariate)
- `rg` a vector containing the end-points of the interval to be searched for the root; in a $c(a, b)$ form
- `tol` the desired accuracy (convergence tolerance)
- `interact` logical; whether choose the end-points by clicking on the curve (for two times) directly?
- `xlab`, `ylab`, `main` axis and main titles to be used in the plot
- `...` other arguments passed to `curve`

**Details**

Suppose we want to solve the equation $f(x) = 0$. Given two points $a$ and $b$ such that $f(a)$ and $f(b)$ have opposite signs, we know by the intermediate value theorem that $f$ must have at least one root in the interval $[a, b]$ as long as $f$ is continuous on this interval. The bisection method divides the interval in two by computing $c = (a + b)/2$. There are now two possibilities: either $f(a)$ and $f(c)$ have opposite signs, or $f(c)$ and $f(b)$ have opposite signs. The bisection algorithm is then applied recursively to the sub-interval where the sign change occurs.

During the process of searching, the mid-point of subintervals are annotated in the graph by both texts and blue straight lines, and the end-points are denoted in dashed red lines. The root of each iteration is also plotted in the right margin of the graph.
Value

A list containing

- root: the root found by the algorithm
- value: the value of \( \text{FUN}(\text{root}) \)
- iter: number of iterations; if it is equal to \( \text{ani.options('nmax')} \), it’s quite likely that the root is not reliable because the maximum number of iterations has been reached

Note

The maximum number of iterations is specified in \( \text{ani.options('nmax')} \).

---

**BM.circle**  
*Brownian Motion in a circle*

Description

Several points moving randomly in a circle.

Usage

`BM.circle(n = 20, col = rainbow(n), ...)`

Arguments

- `n`: number of points
- `col`: colors of points
- `...`: other parameters passed to points
Details

This is a solution to the question raised in R-help: https://stat.ethz.ch/pipermail/r-help/2008-December/183018.html.

Value

Invisible NULL.

Note

The maximum number of steps in the motion is specified in ani.options('nmax').

Author(s)

Yihui Xie

References

Examples at https://yihui.name/animation/example/bm-circle/

See Also

brownian.motion, rnorm

---

**boot.iid**

*Demonstrate bootstrapping for iid data*

Description

Use a sunflower scatter plot to illustrate the results of resampling, and a histogram to show the distribution of the statistic of interest.

Usage

```r
boot.iid(x = runif(20), statistic = mean, m = length(x), mat = matrix(1:2, 2),
          widths = rep(1, ncol(mat)), heights = rep(1, nrow(mat)), col = c("black", "red",
          "bisque", "red", "gray"), cex = c(1.5, 0.8), main, ...)
```

Arguments

- `x`: a numerical vector (the original data).
- `statistic`: A function which returns a value of the statistic of interest when applied to the data `x`.
- `m`: the sample size for bootstrapping (m-out-of-n bootstrap)
- `mat`, `widths`, `heights`: arguments passed to `layout` to set the layout of the two graphs
col
da character vector of length 5 specifying the colors of: points of original data, points for the sunflowerplot, rectangles of the histogram, the density line, and the rug.

cex
a numeric vector of length 2: magnification of original data points and the sunflowerplot points.

main
a character vector of length 2: the main titles of the two graphs.

...other arguments passed to hist

Details
This is actually a very naive version of bootstrapping but may be useful for novices. By default, the circles denote the original dataset, while the red sunflowers (probably) with leaves denote the points being resampled; the number of leaves just means how many times these points are resampled, as bootstrap samples with replacement. The x-axis is the sample values, and y-axis is the indices of sample points.

The whole process has illustrated the steps of resampling, computing the statistic and plotting its distribution based on bootstrapping.

Value
A list containing

t0 The observed value of 'statistic' applied to 'x'.

tstar Bootstrap versions of the 'statistic'.

Note
The maximum times of resampling is specified in ani.options('nmax').

Author(s)
Yihui Xie

References
Examples at https://yihui.name/animation/example/boot-iid/

There are many references explaining the bootstrap and its variations.

See Also

sunflowerplot
**boot.lowess**  

*Bootstrapping with LOWESS*

**Description**

Sample the original data with replacement and fit LOWESS curves accordingly.

**Usage**

```r
boot.lowess(x, y = NULL, f = 2/3, iter = 3, line.col = "#FF000033", ...)
```

**Arguments**

- `x, y, f, iter` passed to `lowess`
- `line.col` the color of the LOWESS lines
- `...` other arguments passed to the scatterplot by `plot`

**Details**

We keep on resampling the data and finally we will see several bootstrapped LOWESS curves, which may give us a rough idea about a “confidence interval” of the LOWESS fit.

**Author(s)**

Yihui Xie

**References**

Examples at [https://yihui.name/animation/example/boot-lowess/](https://yihui.name/animation/example/boot-lowess/)

---

**brownian.motion**  

*Demonstration of Brownian motion on the 2D plane*

**Description**

Brownian motion, or random walk, can be regarded as the trace of some cumulative normal random numbers.

**Usage**

```r
brownian.motion(n = 10, xlim = c(-20, 20), ylim = c(-20, 20), ...)
```
Arguments

- **n**: Number of points in the scatterplot
- **xlim, ylim**: Arguments passed to `plot.default` to control the appearance of the scatterplot (title, points, etc), see `points` for details.
- **...**: other arguments passed to `plot.default`

Details

The location of the next step is “current location + random Gaussian numbers”, i.e.,

\[
x_{k+1} = x_k + \text{rnorm}(1)
\]

\[
y_{k+1} = y_k + \text{rnorm}(1)
\]

where \((x, y)\) stands for the location of a point.

Value

None (invisible `NULL`).

Note

The maximum number of steps in the motion is specified in `ani.options('nmax')`.

Author(s)

Yihui Xie

References

Examples at [https://yihui.name/animation/example/brownian-motion/](https://yihui.name/animation/example/brownian-motion/)

See Also

`rnorm`
**Simulation of Buffon’s Needle**

**Description**

This function provides a simulation for the problem of Buffon’s Needle, which is one of the oldest problems in the field of geometrical probability.

**Usage**

```r
buffon.needle(l = 0.8, d = 1, redraw = TRUE, mat = matrix(c(1, 3, 2, 3), 2),
              heights = c(3, 2), col = c("lightgray", "red", "gray", "red", "blue", "black",
                         "red"), expand = 0.4, type = "1", ...)
```

**Arguments**

- `l` numerical. length of the needle; shorter than `d`.
- `d` numerical. distances between lines; it should be longer than `l`.
- `redraw` logical. redraw former ‘needles’ or not for each drop.
- `mat`, `heights` arguments passed to `layout` to set the layout of the three graphs.
- `col` a character vector of length 7 specifying the colors of: background of the area between parallel lines, the needles, the sin curve, points below / above the sin curve, estimated π values, and the true π value.
- `expand` a numerical value defining the expanding range of the y-axis when plotting the estimated π values: the ylim will be (1 +/- expand) * pi.
- `type` an argument passed to `plot` when plotting the estimated π values (default to be lines).
- ... other arguments passed to `plot` when plotting the values of estimated π.

**Details**

This is quite an old problem in probability. For mathematical background, please refer to [http://en.wikipedia.org/wiki/Buffon%27s_needle](http://en.wikipedia.org/wiki/Buffon%27s_needle) or [http://www.mste.uiuc.edu/reese/buffon/buffon.html](http://www.mste.uiuc.edu/reese/buffon/buffon.html).

‘Needles’ are denoted by segments on the 2D plane, and dropped randomly to check whether they cross the parallel lines. Through many times of ‘dropping’ needles, the approximate value of π can be calculated out.

There are three graphs made in each step: the top-left one is a simulation of the scenario, the top-right one is to help us understand the connection between dropping needles and the mathematical method to estimate π, and the bottom one is the result for each drop.

**Value**

The values of estimated π are returned as a numerical vector (of length `nmax`).
Note

Note that `redraw` has great influence on the speed of the simulation (animation) if the control argument `nmax` (in `ani.options`) is quite large, so you’d better specify it as FALSE when doing a large amount of simulations.

The maximum number of drops is specified in `ani.options('nmax')`.

Author(s)

Yihui Xie

References

Examples at https://yihui.name/animation/example/buffon-needle/

Description

Cleveland Cavaliers played against Los Angeles Lakers at Staples Center in LA on Dec 25, 2009 and won the game by 102:87. This data recorded the locations of players on the court and the results of the shots.

Format

A data frame with 455 observations on the following 7 variables.

- `player`: a character vector: the current player
- `time`: a character vector: the time
- `period`: a numeric vector: the period (1 - 4)
- `realx`: a numeric vector: the x-axis location
- `realy`: a numeric vector: the y-axis location
- `result`: a factor with levels made and missed
- `team`: a factor with levels CLE, LAL and OFF

Note

We view the court with CLE in the left and LAL in the right: `realx` is the distance to the left border of CLE’s court, and `realy` is the distance to the bottom border of the court; notice that the size of the court is $94 \times 50$ (feet).
Demonstration of the Central Limit Theorem

Description

First of all, a number of observations are generated from a certain distribution for each variable \(X_j, j = 1, 2, \ldots, n\), and \(n = 1, 2, \ldots, n_{max}\), then the sample means are computed, and at last the density of these sample means is plotted as the sample size \(n\) increases (the theoretical limiting distribution is denoted by the dashed line), besides, the P-values from the normality test `shapiro.test` are computed for each \(n\) and plotted at the same time.

Usage

```r
clt.ania(n = 300, FUN = rexp, mean = 1, sd = 1, col = c("bisque", "red", "blue", "black"), mat = matrix(1:2, 2), widths = rep(1, ncol(mat)), heights = rep(1, nrow(mat)), xlim, ...)
```

Arguments

- **obs**: the number of sample means to be generated from the distribution based on a given sample size \(n\); these sample mean values will be used to create the histogram
- **FUN**: the function to generate \(n\) random numbers from a certain distribution
- **mean, sd**: the expectation and standard deviation of the population distribution (they will be used to plot the density curve of the theoretical Normal distribution with mean equal to \(\text{mean}\) and \(\text{sd}\) equal to \(sd/\sqrt{n}\); if any of them is NA, the density curve will be suppressed)
- **col**: a vector of length 4 specifying the colors of the histogram, the density curve of the sample mean, the theoretical density curve and P-values.
- **mat, widths, heights**: arguments passed to `layout` to set the layout of the two graphs.
- **xlim**: the x-axis limit for the histogram (it has a default value if not specified)
- **...**: other arguments passed to `plot.default` to plot the P-values

Details

As long as the conditions of the Central Limit Theorem (CLT) are satisfied, the distribution of the sample mean will be approximate to the Normal distribution when the sample size \(n\) is large enough, no matter what is the original distribution. The largest sample size is defined by \(n_{max}\) in `ani.options`.

Source

http://www.basketballgeek.com/data/ (transformed based on the original data)

Examples

```r
## see demo('CLEvsLAL', package = 'animation') for a 'replay' of the game
```
**Value**

A data frame of P-values.

### conf.int

**Demonstration of the concept of confidence intervals**

**Description**

This function gives a demonstration of the concept of confidence intervals in mathematical statistics.

**Usage**

```r
conf.int(level = 0.95, size = 50, cl = c("red", "gray"), ...)
```

**Arguments**

- `level`: the confidence level \((1 - \alpha)\), e.g. 0.95
- `size`: the sample size for drawing samples from \(N(0, 1)\)
- `cl`: two different colors to annotate whether the confidence intervals cover the true mean (\(cl[1]\): no; \(cl[2]\): yes)
- `...`: other arguments passed to `plot.default`

**Details**

Keep on drawing samples from the Normal distribution \(N(0, 1)\), computing the intervals based on a given confidence level and plotting them as segments in a graph. In the end, we may check the coverage rate against the given confidence level.

Intervals that cover the true parameter are denoted in color \(cl[2]\), otherwise in color \(cl[1]\). Each time we draw a sample, we can compute the corresponding confidence interval. As the process of drawing samples goes on, there will be a legend indicating the numbers of the two kinds of intervals respectively and the coverage rate is also denoted in the top-left of the plot.

The argument `nmax` in `ani.options` controls the maximum times of drawing samples.
Value

A list containing

- **level**: confidence level
- **size**: sample size
- **CI**: a matrix of confidence intervals for each sample
- **CR**: coverage rate

cv.ani

*Demonstration for the process of cross-validation*

Description

This function uses rectangles to illustrate the $k$ folds and mark the test set and the training set with different colors.

Usage

```r
cv.ani(x = runif(150), k = 10, col = c("green", "red", "blue"), pch = c(4, 1), ...)
```

Arguments

- **x**: a numerical vector which stands for the sample points.
- **k**: an integer: how many parts should we split the data into? (comes from the $k$-fold cross-validation.)
- **col**: a character vector of length 3 specifying the colors of: the rectangle representing the test set, the points of the test set, and points of the training set.
- **pch**: a numeric vector of length 2 specifying the symbols of the test set and training set respectively.
- **...**: other arguments passed to `plot.default`

Details

Briefly speaking, the process of cross-validation is just to split the whole data set into several parts and select one part as the test set and the rest parts as the training set.

The computation of sample sizes is base on `kfcv`. 
cv.nfeaturesLDA

Value

None (invisible NULL).

Note

For the 'leave-one-out' cross-validation, just specify k as length(x), then the rectangles will 'shrink' into single lines.

The final number of animation frames is the smaller one of ani.options('nmax') and k.

This function has nothing to do with specific models used in cross-validation.

cv.nfeaturesLDA | Cross-validation to find the optimum number of features (variables) in LDA

Description

This function provides an illustration of the process of finding out the optimum number of variables using k-fold cross-validation in a linear discriminant analysis (LDA).

Usage

cv.nfeaturesLDA(data = matrix(rnorm(600), 60), cl = gl(3, 20), k = 5, cex.rg = c(0.5, 3), col.av = c("blue", "red"), ...)

Arguments

data | a data matrix containing the predictors in columns
cl | a factor indicating the classification of the rows of data
k | the number of folds
cex.rg | the range of the magnification to be used to the points in the plot
col.av | the two colors used to respectively denote rates of correct predictions in the i-th fold and the average rates for all k folds
... | arguments passed to points to draw the points which denote the correct rate
Details

For a classification problem, usually we wish to use as less variables as possible because of difficulties brought by the high dimension.

The selection procedure is like this:

• Split the whole data randomly into $k$ folds:
  – For the number of features $g = 1, 2, \ldots, g_{max}$, choose $g$ features that have the largest discriminatory power (measured by the F-statistic in ANOVA):
    * For the fold $i$ ($i = 1, 2, \ldots, k$):
      - Train a LDA model without the $i$-th fold data, and predict with the $i$-th fold for a proportion of correct predictions $p_g$;
    – Average the $k$ proportions to get the correct rate $p_g$;
  • Determine the optimum number of features with the largest $p$.

Note that $g_{max}$ is set by ani.options('rmax') (i.e. the maximum number of features we want to choose).

Value

A list containing

- accuracy: a matrix in which the element in the i-th row and j-th column is the rate of correct predictions based on LDA, i.e. build a LDA model with j variables and predict with data in the i-th fold (the test set)
- optimum: the optimum number of features based on the cross-validation

ecol.death.sim

A simulation of the death of two species with certain probabilities

Description
Suppose there are two plant species in a field: A and B. One of them will die at each time and a new plant will grow in the place where the old plant died; the species of the new plant depends on the proportions of two species: the larger the proportion is, the greater the probability for this species to come up will be.

Usage
ecol.death.sim(nr = 10, nc = 10, num.sp = c(50, 50), col.sp = c(1, 2), pch.sp = c(1, 2), col.die = 1, pch.die = 4, cex = 3, ...)

Arguments
nr, nc number of rows and columns of the field (plants grow on a nr x nc grid)
num.sp number of two plants respectively
col.sp, pch.sp colors and point symbols of the two species respectively
col.die, pch.die, cex the color, point symbol and magnification to annotate the plant which dies (symbol default to be an ‘X’)
... other arguments passed to plot to set up the plot

Value
a vector (factor) containing 1’s and 2’s, denoting the plants finally survived

Note
2 * ani.options('nmax') image frames will actually be produced.

Author(s)
Yihui Xie

References
This animation is motivated by a question raised from Jing Jiao, a student in biology, to show the evolution of two species.
The original post is in the forum of the “Capital of Statistics”: http://cos.name/cn/topic/14093 (in Chinese)
Examples

```r
oopt = ani.options(nmax = ifelse(interactive(), 50, 2), interval = 0.3)
par(ann = FALSE, mar = rep(0, 4))
ecol.death.sim()

## large scale simulation
ani.options(nmax = ifelse(interactive(), 1000, 2), interval = 0.02)
ecol.death.sim(col.sp = c(8, 2), pch.sp = c(20, 17))
ani.options(oopt)
```

---

**flip.coin**  
*Probability in flipping coins*

### Description

This function provides a simulation to the process of flipping coins and computes the frequencies for ‘heads’ and ‘tails’.

### Usage

```r
flip.coin(faces = 2, prob = NULL, border = "white", grid = "white", col = 1:2,
          type = "p", pch = 21, bg = "transparent", digits = 3)
```

### Arguments

- **faces**: an integer or a character vector. See details below.
- **prob**: the probability vector of showing each face. If NULL, each face will be shown in the same probability.
- **border**: The border style for the rectangles which stand for probabilities.
- **grid**: the color for horizontal grid lines in these rectangles
- **col**: The colors to annotate different faces of the ‘coin’.
- **type, pch, bg**: See `points`.
- **digits**: integer indicating the precision to be used in the annotation of frequencies in the plot

### Details

If `faces` is a single integer, say 2, a sequence of integers from 1 to `faces` will be used to denote the faces of a coin; otherwise this character vector just gives the names of each face.

When the `i`-th face shows up, a colored thin rectangle will be added to the corresponding place (the `i`-th bar), and there will be corresponding annotations for the number of tosses and frequencies.
The special argument `grid` is for consideration of a too large number of flipping, in which case if you still draw horizontal lines in these rectangles, the rectangles will be completely covered by these lines, thus we should specify it as `NA`.

At last the frequency for each face will be computed and shown in the header of the plot – this shall be close to `prob` if `ani.options('nmax')` is large enough.

### Value

A list containing

- `freq`: A vector of frequencies (simulated probabilities)
- `nmax`: the total number of tosses

### Note

You may change the colors of each face using the argument `col` (repeated if shorter than the number of faces).

### Author(s)

Yihui Xie

**g.brownian.motion**  
**Brownian Motion using Google Visualization API**

### Description

We can use R to generate random numbers from the Normal distribution and write them into an HTML document, then the Google Visualization gadget “motionchart” will prepare the animation for us (a Flash animation with several buttons).

### Usage

```
g.brownian.motion(p = 20, start = 1900, digits = 14, file = "index.html", width = 800, height = 600)
```
Arguments

- **p**: number of points
- **start**: start “year”; it has no practical meaning in this animation but it’s the required by the Google gadget
- **digits**: the precision to round the numbers
- **file**: the HTML filename
- **width, height**: width and height of the animation

Value

NULL. An HTML page will be opened as the side effect.

Note

The number of frames is controlled by `ani.options('nmax')` as usual.

Due to the “security settings” of Adobe Flash player, you might not be able to view the generated Flash animation locally, i.e. using an address like ‘file:///C:/Temp/index.html’. In this case, you can upload the HTML file to a web server and use the http address to view the Flash file.

brownian.motion, BM.circle, rnorm

Examples

```r
g.brownian.motion(15, digits = 2, width = 600, height = 500, file = "BM-motion-chart.html")
```

Description

This function provides a visual illustration for the process of minimizing a real-valued function through Gradient Descent Algorithm.
Usage

grad.desc(FUN = function(x, y) x^2 + 2 * y^2, rg = c(-3, -3, 3, 3), init = c(-3, 3), gamma = 0.05, tol = 0.001, gr = NULL, len = 50, interact = FALSE, col.contour = "red", col.arrow = "blue", main)

Arguments

FUN: a bivariate objective function to be minimized (variable names do not have to be x and y); if the gradient argument gr is NULL, deriv will be used to calculate the gradient, in which case we should not put braces around the function body of FUN (e.g. the default function is function(x, y) x^2 + 2 * y^2)

rg: ranges for independent variables to plot contours; in a c(x0,y0, x1, y1) form

init: starting values

gamma: size of a step

tol: tolerance to stop the iterations, i.e. the minimum difference between F(x_i) and F(x_{i+1})

gr: the gradient of FUN; it should be a bivariate function to calculate the gradient (not the negative gradient!) of FUN at a point (x, y), e.g. function(x, y) 2 * x + 4 * y. If it is NULL, R will use deriv to calculate the gradient

len: desired length of the independent sequences (to compute z values for contours)

interact: logical; whether choose the starting values by clicking on the contour plot directly?

col.contour, col.arrow: colors for the contour lines and arrows respectively (default to be red and blue)

main: the title of the plot; if missing, it will be derived from FUN

Details

Gradient descent is an optimization algorithm. To find a local minimum of a function using gradient descent, one takes steps proportional to the negative of the gradient (or the approximate gradient) of the function at the current point. If instead one takes steps proportional to the gradient, one approaches a local maximum of that function; the procedure is then known as gradient ascent.

The arrows are indicating the result of iterations and the process of minimization; they will go to a local minimum in the end if the maximum number of iterations ani.options('nmax') has not been reached.

Value

A list containing

par: the solution for the local minimum

value: the value of the objective function corresponding to par

iter: the number of iterations; if it is equal to ani.options('nmax'), it's quite likely that the solution is not reliable because the maximum number of iterations has been reached
HuSpeech  29

<table>
<thead>
<tr>
<th>gradient</th>
<th>the gradient function of the objective function</th>
</tr>
</thead>
<tbody>
<tr>
<td>persp</td>
<td>a function to make the perspective plot of the objective function; can accept further arguments from persp (see the examples below)</td>
</tr>
</tbody>
</table>

**Note**

Please make sure the function FUN provided is differentiable at init, what's more, it should also be 'differentiable' using deriv if you do not provide the gradient function gr.

If the arrows cannot reach the local minimum, the maximum number of iterations nmax in ani.options may need to be increased.

im.convert
A wrapper for the ‘convert’ utility of ImageMagick or GraphicsMagick

Description
The main purpose of these two functions is to create GIF animations.

Usage
im.convert(files, output = "animation.gif", convert = c("magick", "convert", "gm convert"), cmd.fun = if (.Platform$OS.type == "windows") shell else system, extra.opts = "", clean = FALSE)
gm.convert(..., convert = "gm convert")

Arguments
files either a character vector of file names, or a single string containing wildcards (e.g. 'Rplot*.png')
output the file name of the output (with proper extensions, e.g. gif)
convert the convert command; it must be 'magick', 'convert' or 'gm convert'; and it can be pre-specified as an option in ani.options('convert'), e.g. (Windows users) ani.options(convert = 'c:/program files/imagemagick/convert.exe'), or (Mac users) ani.options(convert = '/opt/local/bin/convert'); see the Note section for more details
cmd.fun a function to invoke the OS command; by default system
The function `im.convert` simply wraps the arguments of the `convert` utility of ImageMagick to make it easier to call ImageMagick in R;

The function `gm.convert` is a wrapper for the command `gm convert` of GraphicsMagick.

Details

The function `im.convert` simply wraps the arguments of the `convert` utility of ImageMagick to make it easier to call ImageMagick in R;

The function `gm.convert` is a wrapper for the command `gm convert` of GraphicsMagick.

Value

The command for the conversion.

If `ani.options('autobrowse') == TRUE`, this function will also try to open the output automatically.

Note

If `files` is a character vector, please make sure the order of filenames is correct! The first animation frame will be `files[1]`, the second frame will be `files[2]`, ...

Both ImageMagick and GraphicsMagick may have a limit on the number of images to be converted. It is a known issue that this function can fail with more than (approximately) 9000 images. The function `saveVideo` is a better alternative in such a case.

Most Windows users do not have read the boring notes below after they have installed ImageMagick or GraphicsMagick. For the rest of Windows users:

**ImageMagick users** Please install ImageMagick from [http://www.imagemagick.org](http://www.imagemagick.org), and make sure the the path to `convert.exe` is in your `PATH` variable, in which case the command `convert` can be called without the full path. Windows users are often very confused about the ImageMagick and `PATH` setting, so I’ll try to search for ImageMagick in the Registry Hive by `readRegistry('SOFTWARE\ImageMagick\Current')$BinPath`, thus you might not really need to modify your `PATH` variable.

For Windows users who have installed LyX, I will also try to find the `convert` utility in the LyX installation directory, so they do not really have to install ImageMagick if LyX exists in their system (of course, the LyX should be installed with ImageMagick).

Once the `convert` utility is found, the animation option `convert` will be set (`ani.options(convert = 'path/to/convert.exe')`); this can save time for searching for `convert` in the operating system next time.

**GraphicsMagick users** During the installation of GraphicsMagick, you will be asked if you allow it to change the `PATH` variable; please do check the option.

A reported problem is `cmd.fun = shell` might not work under Windows but `cmd.fun = system` works fine. Try this option in case of failures.

---

**kfcv**

Sample sizes for k-fold cross-validation

Description

Compute sample sizes for \(k\)-fold cross-validation.

Usage

```
kfcv(k, N)
```

Arguments

- \(k\) number of groups.
- \(N\) total sample size.

Details

If \(N/k\) is an integer, the sample sizes are \(k \times N/k\)'s \((N/k, N/k, \ldots)\), otherwise the remainder will be allocated to each group as 'uniformly' as possible, and at last these sample sizes will be permuted randomly.

Value

A vector of length \(k\) containing \(k\) sample sizes.

Author(s)

Yihui Xie

See Also

cv.ani
Examples

```r
## divisible
kfcv(5, 25)

## not divisible
kfcv(10, 77)
```

**Description**

This function provides a demo of the k-Means cluster algorithm for data containing only two variables (columns).

**Usage**

```r
def kmeans.ani(x = cbind(x1 = runif(50), x2 = runif(50)), centers = 3,
hints = c("Move centers!", "Find cluster?") , pch = 1:3, col = 1:3)
```

**Arguments**

- `x`: A numerical matrix or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns) containing only 2 columns.
- `centers`: Either the number of clusters or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in `x` is chosen as the initial centres.
- `hints`: Two text strings indicating the steps of k-means clustering: move the center or find the cluster membership?
- `pch, col`: Symbols and colors for different clusters; the length of these two arguments should be equal to the number of clusters, or they will be recycled.

**Details**

The k-Means cluster algorithm may be regarded as a series of iterations of: finding cluster centers, computing distances between sample points, and redefining cluster membership.

The data given by `x` is clustered by the $k$-means method, which aims to partition the points into $k$ groups such that the sum of squares from points to the assigned cluster centers is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

**Value**

A list with components

- `cluster`: A vector of integers indicating the cluster to which each point is allocated.
- `centers`: A matrix of cluster centers.
Note

This function is only for demonstration purpose. For practical applications please refer to `kmeans`.

Note that `ani.options('nmax')` is defined as the maximum number of iterations in such a sense: an iteration includes the process of computing distances, redefining membership and finding centers. Thus there should be $2 \times \text{ani.options('nmax')}$ animation frames in the output if the other condition for stopping the iteration has not yet been met (i.e. the cluster membership will not change any longer).

Author(s)

Yihui Xie

References

Examples at https://yihui.name/animation/example/kmeans-ani/

See Also

`kmeans`

---

**knn.ani**  
*Demonstration of the k-Nearest Neighbour classification*

Description

Demonstrate the process of k-Nearest Neighbour classification on the 2D plane.

Usage

```r
knn.ani(train, test, cl, k = 10, interact = FALSE, tt.col = c("blue", "red"),
  cl.pch = seq_along(unique(cl)), dist.lty = 2, dist.col = "gray", knn.col = "green",
  ...)```

Arguments

- `train` matrix or data frame of training set cases containing only 2 columns
- `test` matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case. It should also contain only 2 columns. This data set will be ignored if `interact = TRUE`; see `interact` below.
- `cl` factor of true classifications of training set
- `k` number of neighbours considered.
- `interact` logical. If TRUE, the user will have to choose a test set for himself using mouse click on the screen; otherwise compute kNN classification based on argument `test`.
- `tt.col` a vector of length 2 specifying the colors for the training data and test data.
For each row of the test set, the $k$ nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. For a single test sample point, the basic steps are:

1. locate the test point
2. compute the distances between the test point and all points in the training set
3. find $k$ shortest distances and the corresponding training set points
4. vote for the result (find the maximum in the table for the true classifications)

As there are four steps in an iteration, the total number of animation frames should be $4 \times \min(nrow(test), ani.options('nmax'))$ at last.

Value

A vector of class labels for the test set.

Note

There is a special restriction (only two columns) on the training and test data set just for sake of the convenience for making a scatterplot. This is only a rough demonstration; for practical applications, please refer to existing kNN functions such as `knn` in `class`, etc.

If either one of `train` and `test` is missing, there’ll be random matrices prepared for them. (It’s the same for `cl`.)

Author(s)

Yihui Xie

References

Examples at https://yihui.name/animation/example/knn-ani/

See Also

knn
Description

This is a simple demonstration of the meaning of least squares in univariate linear regression.

Usage

```r
least.squares(x, y, n = 15, ani.type = c("slope", "intercept"), a, b, a.range, b.range,
ab.col = c("gray", "black"), est.pch = 19, v.col = "red", v.lty = 2, rss.pch = 19,
rss.type = "o", mfrow = c(1, 2), ...)
```

Arguments

- `x`: a numeric vector: the independent variable
- `y`: a numeric vector: the dependent variable
- `n`: the sample size: when `x` and `y` are missing, we use simulated values of `y` (`x = 1:n` and `y = a + b * x + rnorm(n)`) 
- `ani.type`: 'slope': the slope is changing with the intercept fixed; 'intercept': intercept changing and slope fixed
- `a, b`: the fixed intercept and slope; depending on `ani.type`, we only need to specify one of them; e.g. when `ani.type == 'slope'`, we need to specify the value of `a`
- `a.range, b.range`: a vector of length 2 to define the range of the intercept and the slope; only one of them need to be specified; see above
- `ab.col`: the colors of two lines: the real regression line and the moving line with either intercept or slope changing
- `est.pch`: the point character of the 'estimated' values given `x`
- `v.col, v.lty`: the color and line type of the vertical lines which demonstrate the residuals
- `rss.pch, rss.type`: the point character and plot type of the residual plot
- `mfrow`: defines the layout of the graph; see `par`
- `...`: other parameters passed to `plot` to define the appearance of the scatterplot

Details

With either the intercept or the slope changing, the lines will be moving in the graph and corresponding residuals will be plotted. We can finally see the best estimate of the intercept and the slope from the residual plot.
Value

The value returned depends on the animation type.

If it is a slope animation, the value will be a list containing

- `lmfit` the estimates of the intercept and slope with `lm`
- `anifit` the estimate of the slope in the animation

If it is an intercept animation, the second component of the above list will be the estimate of the intercept.

Note the estimate will not be precise generally.

Note

`ani.options('nmax')` specifies the maximum number of steps for the slope or intercept to move.

Author(s)

Yihui Xie

References

Examples at https://yihui.name/animation/example/least-squares/

See Also

- `lm`

Description

This function plots the sample mean as the sample size grows to check whether the sample mean approaches to the population mean.

Usage

```r
lln.ani(FUN = rnorm, mu = 0, np = 30, pch = 20, col.poly = "bisque", col.mu = "gray", 
        ...)
```
Arguments

- **FUN**: a function to generate random numbers from a certain distribution: `function(n, mu)`
- **mu**: population mean; passed to `FUN`
- **np**: times for sampling from a distribution (not the sample size!); to examine the behaviour of the sample mean, we need more times of sampling to get a series of mean values
- **pch**: symbols for points; see Details
- **col.poly**: the color of the polygon to annotate the range of sample means
- **col.mu**: the color of the horizontal line which denotes the population mean
- **...**: other arguments passed to `points`

Details

np points are plotted to denote the distribution of the sample mean; we will observe that the range of the sample mean just becomes smaller and smaller as the sample size increases and ultimately there will be an obvious trend that the sample mean converges to the population mean mu.

The parameter `nmax` in `ani.options` means the maximum sample size.

Value

None (invisible NULL).

Note

The argument `pch` will influence the speed of plotting, and for a very large sample size (say, 300), it is suggested that this argument be specified as `.`.

**MC.hitormiss**  
*Hit or Miss Monte Carlo integration*

Description

Integrate a function using the Hit-or-Miss Monte Carlo algorithm.

Usage

```
MC.hitormiss(FUN = function(x) x - x^2, n = ani.options("nmax"), from = 0, to = 1,  
col.points = c("black", "red"), pch.points = c(20, 4), ...)  
```
Arguments

- **FUN**: the function to be integrated
- **n**: number of points to be sampled from the Uniform\((0, 1)\) distribution
- **from**, **to**: the limits of integration
- **col.points**, **pch.points**: colors and point characters for points which “hit” or “miss” the area under the curve
- **...**: other arguments passed to `points`

Details

We compute the proportion of points hitting the area under the curve, and the integral can be estimated by the proportion multiplied by the total area of the rectangle (from xmin to xmax, ymin to ymax).

Value

A list containing

- **x1**: the Uniform random numbers generated on x-axis
- **x2**: the Uniform random numbers generated on y-axis
- **y**: function values evaluated at x1
- **n**: number of points drawn from the Uniform distribution
- **est**: the estimated value of the integral

Note

This function is for demonstration purpose only; the integral might be very inaccurate when n is small.

`ani.options('nmax')` specifies the maximum number of trials.

See Also

`integrate, MC.samplemean`
**MC.samplemean**  
*Sample Mean Monte Carlo integration*

**Description**
Integrate a function from 0 to 1 using the Sample Mean Monte Carlo algorithm

**Usage**
```r
MC.samplemean(FUN = function(x) x - x^2, n = ani.options("nmax"), col.rect = c("gray", "black"), adj.x = TRUE, ...)
```

**Arguments**
- **FUN**  the function to be integrated
- **n**  number of points to be sampled from the Uniform(0, 1) distribution
- **col.rect**  colors of rectangles (for the past rectangles and the current one)
- **adj.x**  should the locations of rectangles on the x-axis be adjusted? If TRUE, the rectangles will be laid side by side and it is informative for us to assess the total area of the rectangles, otherwise the rectangles will be laid at their exact locations.
- **...**  other arguments passed to `rect`

**Details**
*Sample Mean Monte Carlo* integration can compute

\[ I = \int_0^1 f(x) dx \]

by drawing random numbers \( x_i \) from Uniform(0, 1) distribution and average the values of \( f(x_i) \). As \( n \) goes to infinity, the sample mean will approach to the expectation of \( f(X) \) by Law of Large Numbers.

The height of the \( i \)-th rectangle in the animation is \( f(x_i) \) and the width is \( 1/n \), so the total area of all the rectangles is \( \sum f(x_i)1/n \), which is just the sample mean. We can compare the area of rectangles to the curve to see how close is the area to the real integral.

**Value**
A list containing
- **x**  the Uniform random numbers
- **y**  function values evaluated at \( x \)
- **n**  number of points drawn from the Uniform distribution
- **est**  the estimated value of the integral
Note
This function is for demonstration purpose only: the integral might be very inaccurate when \( n \) is small.
\( \text{ani.options('nmax'}) \) specifies the maximum number of trials.

integrate, MC.hitormiss

moving.block Cycle through an R object and plot each subset of elements

Description
For a long numeric vector or matrix (or data frame), we can plot only a subset of its elements to take a closer look at its structure. With a moving “block” from the beginning to the end of a vector or matrix or any R objects to which we can apply subset, all elements inside the block are plotted as a line or scatter plot or any customized plots.

Usage
moving.block(dat = runif(100), block, FUN, ...)

Arguments
dat a numeric vector or two-column matrix
block block length (i.e. how many elements are to be plotted in each step)
FUN a plot function to be applied to the subset of data
... other arguments passed to FUN

Details
For a vector, the elements from \( i + 1 \) to \( i + \text{block} \) will be plotted in the \( i \)-th step; similarly for a matrix or data frame, a (scatter) plot will be created from the \( i + 1 \)-th row to \( i + \text{block} \)-th row.
However, this function is not limited to scatter plots or lines – we can customize the function FUN as we wish.
Value

NULL

Note

There will be ani.options('nmax') image frames created in the end. Ideally the relationship between ani.options('nmax') and block should follow this equality: block = length(x) - ani.options('nmax') + 1 (replace length(x) with nrow(x) when x is a matrix). The function will compute block according to the equality by default if no block length is specified.

The three arguments dat, i and block are passed to FUN in case we want to customize the plotting function, e.g. we may want to annotate the x-axis label with i, or we want to compute the mean value of dat[i + 1:block], etc. See the examples below to learn more about how to make use of these three arguments.

Author(s)

Yihui Xie

References

Examples at https://yihui.name(animation/example/moving-block/)

Description

This function just fulfills a very naive idea about moving window regression using rectangles to denote the “windows” and move them, and the corresponding AR(1) coefficients as long as rough confidence intervals are computed for data points inside the “windows” during the process of moving.

Usage

mwar.ani(x, k = 15, conf = 2, mat = matrix(1:2, 2), widths = rep(1, ncol(mat)), heights = rep(1, nrow(mat)), lty.rect = 2, ...)

Arguments

x univariate time-series (a single numerical vector); default to be sin(seq(0, 2 * pi, length = 50)) + rnorm(length(x))

k an integer of the window width

conf a positive number: the confidence intervals are computed as c(ar1 - conf*s.e., ar1 + conf*s.e.)

mat, widths, heights arguments passed to layout to divide the device into 2 parts

lty.rect the line type of the rectangles respresenting the moving “windows”

... other arguments passed to points in the bottom plot (the centers of the arrows)
newton.method

Details

The AR(1) coefficients are computed by \texttt{arima}.

Value

A list containing

\begin{itemize}
  \item \texttt{phi} the AR(1) coefficients
  \item \texttt{L} lower bound of the confidence interval
  \item \texttt{U} upper bound of the confidence interval
\end{itemize}

Author(s)

Yihui Xie

\texttt{arima}

\begin{tabular}{ll}
\texttt{newton.method} & \textit{Demonstration of the Newton-Raphson method for root-finding} \\
\end{tabular}

Description

This function provides an illustration of the iterations in Newton’s method.

Usage

\begin{verbatim}
newton.method(FUN = function(x) x^2 - 4, init = 10, rg = c(-1, 10), tol = 0.001,
             interact = FALSE, col.lp = c("blue", "red", "red"), main, xlab, ylab, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{FUN} the function in the equation to solve (univariate), which has to be defined without braces like the default one (otherwise the derivative cannot be computed)
  \item \texttt{init} the starting point
  \item \texttt{rg} the range for plotting the curve
  \item \texttt{tol} the desired accuracy (convergence tolerance)
  \item \texttt{interact} logical; whether choose the starting point by clicking on the curve (for 1 time) directly?
\end{itemize}
newton.method

col.lp  a vector of length 3 specifying the colors of: vertical lines, tangent lines and points
main, xlab, ylab  titles of the plot; there are default values for them (depending on the form of the function FUN)
...  other arguments passed to curve

Details
Newton’s method (also known as the Newton-Raphson method or the Newton-Fourier method) is an efficient algorithm for finding approximations to the zeros (or roots) of a real-valued function \( f(x) \).

The iteration goes on in this way:

\[
x_{k+1} = x_k - \frac{F\!U\!N(x_k)}{F\!U\!N'(x_k)}
\]

From the starting value \( x_0 \), vertical lines and points are plotted to show the location of the sequence of iteration values \( x_1, x_2, \ldots \); tangent lines are drawn to illustrate the relationship between successive iterations; the iteration values are in the right margin of the plot.

Value
A list containing

root  the root found by the algorithm
value  the value of \( F\!U\!N(\text{root}) \)
iter  number of iterations; if it is equal to \text{ani.options('nmax')}, it’s quite likely that the root is not reliable because the maximum number of iterations has been reached

Note
The algorithm might not converge – it depends on the starting value. See the examples below.

**pdftk**

*A wrapper for the PDF toolkit Pdftk*

---

Description

If the toolkit Pdftk is available in the system, it will be called to manipulate the PDF files (especially to compress the PDF files).

Usage

pdftk(input, operation = NULL, output, other.opts = "compress dont_ask")

Arguments

- **input**: the path of the input PDF file(s)
- **operation**: the operation to be done on the input (default to be NULL)
- **output**: the path of the output (if missing and input is a scalar, output will be the same as input)
- **other.opts**: other options (default to be 'compress dont_ask', i.e. compress the PDF files and do not ask the user for any input)

Details

This is a wrapper to call pdftk. The path of pdftk should be set via `ani.options(pdftk = 'path/to/pdftk')`. See the reference for detailed usage of pdftk.

Value

if `ani.options('pdftk')` is non-NULL, then this function returns the status of the operation (0 for success; see `system`); otherwise a warning will be issued.

**pollen**

*Synthetic dataset about the geometric features of pollen grains*

**Description**

There are 3848 observations on 5 variables. From the 1986 ASA Data Exposition dataset, made up by David Coleman of RCA Labs.

**Format**

A data frame with 3848 observations on the following 5 variables.

- **RIDGE** a numeric vector
- **NUB** a numeric vector
- **CRACK** a numeric vector
- **WEIGHT** a numeric vector
- **DENSITY** a numeric vector

**Source**

collected from Statlib Datasets Archive: [http://lib.stat.cmu.edu/data-expo/](http://lib.stat.cmu.edu/data-expo/)

**Examples**

```r
## some dense points in the center?
plot(pollen[, 1:2], pch = 20, col = rgb(0, 0, 0, 0.1))

## see demo('pollen', package = 'animation') for a 3D demo; truth is there!
```

---

**price.ani**

*Demonstrate stock prices in animations*

**Description**

This function can display the frequencies of stock prices in a certain time span with the span changing.

**Usage**

```r
price.ani(price, time, time.begin = min(time), span = 15 * 60, ..., xlab = "price",
          ylab = "frequency", xlim, ylim, main)
```
Arguments

price  stock prices
time  time corresponding to prices
time.begin  the time for the animation to begin (default to be the minimum time)
span  time span (unit in seconds; default to be 15 minutes)
...  other arguments passed to plot
xlab, ylab, xlim, ylim, main
   they are passed to plot with reasonable default values

Value

invisible NULL

---

**quincunx**

_Demonstration of the Quincunx (Bean Machine/Galton Box)_

Description

Simulates the quincunx with “balls” (beans) falling through several layers (denoted by triangles) and the distribution of the final locations at which the balls hit is denoted by a histogram; `quincunx()` is shows single layer, and `quincunx2()` is a two-stage version of the quincunx.

Usage

```r
quincunx(balls = 200, layers = 15, pch.layers = 2, pch.balls = 19,
         col.balls = sample(colors(), balls, TRUE), cex.balls = 2)
```

```r
quincunx2(balls = 200, layers = 15, pch.layers = 2, pch.balls = 19,
          col.balls = sample(colors(), balls, TRUE), cex.balls = 2)
```

Arguments

- **balls** number of balls
- **layers** number of layers
- **pch.layers** point character of layers; triangles (pch = 2) are recommended
- **pch.balls, col.balls, cex.balls** point character, colors and magnification of balls

Details

The bean machine, also known as the quincunx or Galton box, is a device invented by Sir Francis Galton to demonstrate the law of error and the normal distribution.

When a ball falls through a layer, it can either go to the right or left side with the probability 0.5. At last the location of all the balls will show us the bell-shaped distribution.
Value

A named vector: the frequency table for the locations of the balls. Note the names of the vector are the locations: 1.5, 2.5, ..., layers - 0.5.

Note

The maximum number of animation frames is controlled by ani.options('nmax') as usual, but it is strongly recommended that ani.options(nmax = balls + layers - 2), in which case all the balls will just fall through all the layers and there will be no redundant animation frames.

Rosling.bubbles  The bubbles animation in Hans Rosling's Talk

Description

In Hans Rosling's attractive talk "Debunking third-world myths with the best stats you've ever seen", he used a lot of bubble plots to illustrate trends behind the data over time. This function gives an imitation of those moving bubbles, besides, as this function is based on symbols, we can also make use of other symbols such as squares, rectangles, thermometers, etc.

Usage

Rosling.bubbles(x, y, data, type = c("circles", "squares", "rectangles", "stars", "thermometers", "boxplots"), bg, xlim = range(x), ylim = range(y), main = NULL, xlab = "x", ylab = "y", ..., grid = TRUE, text = 1:ani.options("nmax"), text.col = rgb(0, 0, 0, 0.5), text.cex = 5)

Arguments

x, y  the x and y co-ordinates for the centres of the bubbles (symbols). Default to be 10 uniform random numbers in [0, 1] for each single image frame (so the length should be 10 * ani.options('nmax'))

type, data  the type and data for symbols; see symbols. The default type is circles.

bg, main, xlim, ylim, xlab, ylab, ...  see symbols. Note that bg has default values taking semi-transparent colors.
grid logical; add a grid to the plot?
text a character vector to be added to the plot one by one (e.g. the year in Rosling’s talk)
text.col, text.cex color and magnification of the background text

Details
Suppose we have observations of \( n \) individuals over ani.options(‘nmax’) years. In this animation, the data of each year will be shown in the bubbles (symbols) plot; as time goes on, certain trends will be revealed (like those in Rosling’s talk). Please note that the arrangement of the data for bubbles (symbols) should be a matrix like \( A_{ijk} \) in which \( i \) is the individual id (from 1 to \( n \)), \( j \) denotes the \( j \)-th variable (from 1 to \( p \)) and \( k \) indicates the time from 1 to ani.options(‘nmax’). And the length of \( x \) and \( y \) should be equal to the number of rows of this matrix.

Value
NULL.

---

**sample.cluster** *Demonstration for the cluster sampling*

**Description**
Each rectangle stands for a cluster, and the simple random sampling without replacement is performed for each cluster. All points in the clusters being sampled will be drawn out.

**Usage**
sample.cluster(pop = ceiling(10 * runif(10, 0.2, 1)), size = 3, p.col = c("blue", "red"), p.cex = c(1, 3), ...)
sample.ratio

**Arguments**

- `pop`: a vector for the size of each cluster in the population.
- `size`: the number of clusters to be drawn out.
- `p.col, p.cex`: different colors / magnification rate to annotate the population and the sample
- `...`: other arguments passed to `rect` to annotate the “clusters”

**Value**

None (invisible NULL).

**Author(s)**

Yihui Xie

**References**

Examples at [https://yihui.name/animation/example/sample-cluster/](https://yihui.name/animation/example/sample-cluster/)

**See Also**

- `sample`, `sample.simple`, `sample.ratio`, `sample.strat`, `sample.system`

---

**sample.ratio**  
_Demonstrate the ratio estimation in sampling survey_

**Description**

This function demonstrates the advantage of ratio estimation when further information (ratio) about `x` and `y` is available.

**Usage**

```r
sample.ratio(X = runif(50, 0, 5), R = 1, Y = R * X + rnorm(X), size = length(X)/2,  
p.col = c("blue", "red"), p.cex = c(1, 3), p.pch = c(20, 21), m.col = c("black",  
"gray"), legend.loc = "topleft", ...)
```

**Arguments**

- `X`: the `X` variable (ancillary)
- `R`: the population ratio `Y/X`
- `Y`: the `Y` variable (whose mean we what to estimate)
- `size`: sample size
- `p.col, p.cex, p.pch`: point colors, magnification and symbols for the population and sample respectively
sample.simple

m.col  color for the horizontal line to denote the sample mean of Y
legend.loc  legend location: topleft, topright, bottomleft, bottomright, ... (see legend)
...  other arguments passed to plot.default

Details
From this demonstration we can clearly see that the ratio estimation is generally better than the simple sample average when the ratio $R$ really exists, otherwise ratio estimation may not help.

Value
A list containing

- $X$: X population
- $Y$: Y population
- $R$: population ratio
- $r$: ratio calculated from samples
- $\bar{Y}$: population mean of Y
- $\bar{Y}_{\text{simple}}$: simple sample mean of Y
- $\bar{Y}_{\text{ratio}}$: sample mean of Y via ratio estimation

Author(s)
Yihui Xie

References
Examples at https://yihui.name/animation/example/sample-ratio/

sample, sample.simple, sample.cluster, sample.strat, sample.system

Description
The whole sample frame is denoted by a matrix ($nrow \times ncol$) in the plane just for convenience, and the points being sampled are marked out (by red circles by default). Each member of the population has an equal and known chance of being selected.

Usage

```r
sample.simple(nrow = 10, ncol = 10, size = 15, p.col = c("blue", "red"), p.cex = c(1, 3))
```
sample.strat

Arguments

- `nrow` the desired number of rows of the sample frame.
- `ncol` the desired number of columns of the sample frame.
- `size` the sample size.
- `p.col, p.cex` different colors/magnification rate to annotate the population and the sample

Value

None (invisible NULL).

```

Description

Each rectangle stands for a stratum, and the simple random sampling without replacement is performed within each stratum. The points being sampled are marked out (by red circles by default).

Usage

```
sample.strat(pop = ceiling(10 * runif(10, 0.5, 1)), size = ceiling(pop * runif(length(pop), 0, 0.5)), p.col = c("blue", "red"), p.cex = c(1, 3), ...)
```

Arguments

- `pop` a vector for the size of each stratum in the population.
- `size` a corresponding vector for the sample size in each stratum (recycled if necessary).
- `p.col, p.cex` different colors/magnification rate to annotate the population and the sample
- `...` other arguments passed to `rect` to annotate the “strata”

saveGIF

Convert images to a single animation file (typically GIF) using ImageMagick or GraphicsMagick

Description

This function opens a graphical device (specified in ani.options('ani.dev')) first to generate a sequence of images based on expr, then makes use of the command convert in 'ImageMagick' to convert these images to a single animated movie (as a GIF or MPG file). An alternative software package is GraphicsMagick (use convert = 'gm convert'), which is smaller than ImageMagick.

Usage

saveGIF(expr, movie.name = "animation.gif", img.name = "Rplot", convert = "magick", cmd.fun, clean = TRUE, extra.opts = "", ...)

saveMovie(expr, movie.name = "animation.gif", img.name = "Rplot", convert = "magick", cmd.fun, clean = TRUE, extra.opts = "", ...)

Arguments

- expr: an expression to generate animations; use either the animation functions (e.g. brownian.motion()) in this package or a custom expression (e.g. for(i in 1:10) plot(runif(10), y)
- movie.name: file name of the movie (with the extension)
- img.name: file name of the sequence of images ('pure' name; without any format or extension)
- convert: the command to convert images (default to be convert (i.e. use ImageMagick), but might be imconvert under some Windows platforms); can be gm convert in order to use GraphicsMagick; see the 'Note' section for details
- cmd.fun: a function to invoke the OS command; by default system
- clean: whether to delete the individual image frames
- extra.opts: additional options passed to im.convert
- ...: other arguments passed to ani.options, e.g. ani.height and ani.width, ...

Details

This function calls im.convert (or gm.convert, depending on the argument convert) to convert images to a single animation.

The advantage of this function is that it can create a single movie file, however, there are two problems too: (1) we need a special (free) software ImageMagick or GraphicsMagick; (2) the speed of the animation will be beyond our control, as the interval option is fixed. Other approaches in this package may have greater flexibilities, e.g. the HTML approach (see saveHTML).
saveHTML

See `ani.options` for the options that may affect the output, e.g. the graphics device (including the height/width specifications), the file extension of image frames, and the time interval between image frames, etc. Note that `ani.options('interval')` can be a numeric vector!

Value

The command for the conversion (see `im.convert`).

Note

See `im.convert` for details on the configuration of ImageMagick (typically for Windows users) or GraphicsMagick.

It is recommended to use `ani.pause()` to pause between animation frames in `expr`, because this function will only pause when called in a non-interactive graphics device, which can save a lot of time. See the demo 'Xmas2' for example (demo('Xmas2', package = 'animation')).

`saveGIF` has an alias `saveMovie` (i.e. they are identical); the latter name is for compatibility to older versions of this package (< 2.0-2). It is recommended to use `saveGIF` to avoid confusions between `saveMovie` and `saveVideo`.

Author(s)

Other utilities: `im.convert`, `saveHTML`, `saveLatex`, `saveSWF`, `saveVideo`

Description

This function first records all the plots in the R expression as bitmap images, then inserts them into an HTML page and finally creates the animation using the SciAnimator library.

Usage

```r
saveHTML(expr, img.name = "Rplot", global.opts = "", single.opts = ",
  navigator = ani.options("nmax") <= 100 & ani.options("interval") >=
    0.05, htmlfile = "index.html", ...)
```
Arguments

expr          an R expression to be evaluated to create a sequence of images
img.name     the filename of the images (the real output will be like ‘img.name1.png’, ‘img.name2.png’, ...
             ); this name has to be different for different animations, since it will be used
             as the identifiers for each animation; make it as unique as possible; meanwhile,
             the following characters in img.name will be replaced by _ to make it a legal
             jQuery string:
             "!#$%&'()*+,./:;?@[^{}\~

global.opts   a string: the global options of the animation; e.g. we can specify the default
             theme to be blue using $.fn.scianimator.defaults.theme = ‘blue’; note these op-
             tions must be legal JavaScript expressions (ended by ‘;’)
single.opts   the options for each single animation (if there are multiple ones in one HTML
             page), e.g. to use the dark theme and text labels for buttons:
             ‘utf8’: false, ‘theme’: ‘dark’
             or to remove the navigator panel (the navigator can affect the smoothness of the
             animation when the playing speed is extremely fast (e.g. interval less than
             0.05 seconds)):
             ‘speed’]
             see the reference for a complete list of available options
navigator     whether to show the navigator (like a progress bar); by default, the navigator is
             not shown for performance reasons when the number of images is greater than
             100 or the time interval is smaller than 0.05
htmlfile      the filename of the HTML file
...            other arguments to be passed to ani.options to animation options such as the
time interval between image frames

Details

It mainly uses the SciAnimator library, which is based on jQuery. It has a neat interface (both techn-
ically and visually) and is much easier to use or extend. Moreover, this function allows multiple
animations in a single HTML page – just use the same HTML filename.

Optionally the source code and some session information can be added below the animations for
the sake of reproducibility (specified by the option ani.options('verbose') – if TRUE, the de-
scription, loaded packages, the code to produce the animation, as well as a part of sessionInfo() will
be written in the bottom of the animation; the R code will be highlighted using the Syntax-
Highlighter library for better reading experience).

Value

The path of the HTML output.

Note

Microsoft IE might restrict the HTML page from running JavaScript and try to “protect your secu-
ritv” when you view the animation page, but this is not really a security problem.
saveLatex

When you want to publish the HTML page on the web, you have to upload the associated ‘css’ and ‘js’ folders with the HTML file as well as the images.

For `saveHTML`, `ani.options(`‘description’`)` can be a character vector, in which case this vector will be pasted into a scalar; use ‘\n\n’ in the string to separate paragraphs (see the first example below).

For the users who do not have R at hand, there is a demo in `system.file(‘misc’, ‘Rweb’, ‘demo.html’, package = ‘animation’)` to show how to create animations online without R being installed locally. It depends, however, on whether the Rweb service can be provided for public use in a long period (currently we are using the Rweb at Tama University). See the last example below.

---

**saveLatex**

*Insert animations into a LaTeX document and compile it*

**Description**

Record animation frames and insert them into a LaTeX document with the `animate` package. Compile the document if an appropriate LaTeX command is provided.

**Usage**

```r
saveLatex(expr, nmax, img.name = "Rplot", ani.opts, centering = TRUE,
   caption = NULL, label = NULL, pkg.opts = NULL, documentclass = "article",
   latex.filename = "animation.tex", pdflatex = "pdflatex", install.animate = TRUE,
   overwrite = TRUE, full.path = FALSE, ...)
```

**Arguments**

- `expr` an expression to generate animations; use either the animation functions (e.g. `brownian.motion()`) in this package or a custom expression (e.g. `for(i in 1:10) plot(runif(10), y)

- `nmax` maximum number of animation frames (if missing and the graphics device is a bitmap device, this number will be automatically calculated); note that we do not have to specify `nmax` when using PDF devices.

- `img.name` basename of file names of animation frames; see the Note section for a possible adjustment on `img.name`
ani.options

options to control the behavior of the animation (passed to the LaTeX macro `\animategraphics`; default to be `controls,width=\linewidth`)

centering

logical: whether to center the graph using the LaTeX environment `\begin{center}` and `\end{center}

caption, label

caption and label for the graphics in the figure environment

pkg.options

global options for the `animate` package

documentclass

LaTeX document class; if `NULL`, the output will not be a complete LaTeX document (only the code to generate the PDF animation will be printed in the console); default to be `article`, but we can also provide a complete statement like `\documentclass[a5paper]{article}

latex.filename

file name of the LaTeX document; if an empty string `''`, the LaTeX code will be printed in the console and hence not compiled

pdflatex

the command for pdfLaTeX (set to `NULL` to ignore the compiling)

install.animate

copy the LaTeX style files `animate.sty` and `animfp.sty`? If you have not installed the LaTeX package `animate`, it suffices just to copy these to files.

overwrite

whether to overwrite the existing image frames

full.path

whether to use the full path (TRUE) or relative path (FALSE) for the animation frames; usually the relative path suffices, but sometimes the images and the LaTeX document might not be in the same directory, so `full.path = TRUE` could be useful; in the latter case, remember that you should never use spaces in the filenames or paths!

... other arguments passed to the graphics device `ani.options`(`ani.dev`), e.g. `ani.height` and `ani.width`

Details

This is actually a wrapper to generate a LaTeX document using R. The document uses the LaTeX package called `animate` to insert animations into PDF's. When we pass an R expression to this function, the expression will be evaluated and recorded by a graphics device (typically `png` and `pdf`). At last, a LaTeX document will be created and compiled if an appropriate LaTeX command is provided. And the final PDF output will be opened with the PDF viewer set in `getOption`(`pdfviewer`) if `ani.options`(`autobrowse`) == TRUE.

Value

Invisible `NULL`

Note

This function will detect if it was called in a Sweave environment – if so, `img.name` will be automatically adjusted to `prefix.string-label`, and the LaTeX output will not be a complete document, but rather a single line like

`\animategraphics[ani.options][1/interval]{img.name}{}{}`
This automatic feature can be useful to Sweave users (but remember to set the Sweave option results=tex). See demo('Sweave_animation') for a complete example.

PDF devices are recommended because of their high quality and usually they are more friendly to LaTeX, but the size of PDF files is often much larger; in this case, we may set the option 'qpdf' or 'pdftk' to compress the PDF graphics output. To set the PDF device, use ani.options(ani.dev = 'pdf', ani.type = 'pdf')

So far animations created by the LaTeX package animate can only be viewed with Acrobat Reader (Windows) or acroread (Linux). Other PDF viewers may not support JavaScript (in fact the PDF animation is driven by JavaScript). Linux users may need to install acroread and set options(pdfviewer = 'acroread').

saveSWF Convert images to Flash animations

Description
This function opens a graphical device first to generate a sequence of images based on expr, then makes use of the commands in SWFTools (png2swf, jpeg2swf, pdf2swf) to convert these images to a single Flash animation.

Usage
saveSWF(expr, swf.name = "animation.swf", img.name = "Rplot", swftools = NULL, ...)

Arguments

expr an expression to generate animations; use either the animation functions (e.g. brownian.motion()) in this package or a custom expression (e.g. for(i in 1:10) plot(runif(10), y)

swf.name file name of the Flash file

img.name the base file name of the sequence of images (without any format or extension)

swftools the path of SWFTools, e.g. 'C:/swftools'. This argument is to make sure that png2swf, jpeg2swf and pdf2swf can be executed correctly. If it is NULL, it should be guaranteed that these commands can be executed without the path; anyway, this function will try to find SWFTools from Windows registry even if it is not in the PATH variable.

... other arguments passed to ani.options, e.g. ani.height and ani.width, ...
Value

An integer indicating failure (-1) or success (0) of the converting (refer to `system`).

Note

Please download and install the SWFTools before using this function: [http://www.swftools.org](http://www.swftools.org).
We can also set the path to SWF Tools by `ani.options(swftools = 'path/to/swftools')`.

`ani.options('ani.type')` can only be one of png, pdf and jpeg.

Also note that PDF graphics can be compressed using qpdf or Pdftk (if either one is installed and `ani.options('qpdf')` or `ani.options('pdftk')` has been set); see qpdf or pdftk.

Other utilities: `im.convert`, `saveGIF`, `saveHTML`, `saveLatex`, `saveVideo`
other.opts other options to be passed to ffmpeg, e.g. we can specify the bitrate as other.opts = '-b 400k'
(The default "-pix_fmt yuv420p" is a work-around for a bug in some versions of ffmpeg.)

... other arguments to be passed to ani.options

Details
This function uses system to call FFmpeg to convert the images to a single video. The command line used in this function is: ffmpeg -y -r <1/interval> -i <img.name>%d.<ani.type> other.opts video.name
where interval comes from ani.options('interval'), and ani.type is from ani.options('ani.type').
For more details on the numerous options of FFmpeg, please see the reference.

Some linux systems may use the alternate software 'avconv' instead of 'ffmpeg'. The package will attempt to determine which command is present and set ani.options('ffmpeg') to an appropriate default value. This can be overridden by passing in the ffmpeg argument.

Value
An integer indicating failure (-1) or success (0) of the converting (refer to system).

Note
There are a lot of possibilities in optimizing the video. My knowledge on FFmpeg is very limited, hence the default output by this function could be of low quality or too large. The file 'presets.xml' of WinFF might be a good guide: http://code.google.com/p/winff/.

sim.qqnorm Simulation of QQ plots for the Normal distribution

Description
This demo shows the possible QQ plots created by random numbers generated from a Normal distribution so that users can get a rough idea about how QQ plots really look like.
Usage

```r
sim.qqnorm(n = 20, last.plot = NULL, ...)
```

Arguments

- `n`  
  integer: sample size

- `last.plot`  
  an expression to be evaluated after the plot is drawn, e.g. `expression(abline(0, 1))` to add the diagonal line

- `...`  
  other arguments passed to `qqnorm`

Details

When the sample size is small, it is hard to get a correct inference about the distribution of data from a QQ plot. Even if the sample size is large, usually there are outliers far away from the straight line. Therefore, don’t overinterpret the QQ plots.

Value

`NULL`

### vanke1127

**Stock prices of Vanke Co., Ltd on 2009/11/27**

Description

This is a sample of stock prices of the Vanke Co., Ltd on 2009/11/27.

Format

A data frame with 2831 observations on the following 2 variables.

- **time**  
  POSIXt: the time corresponding to stock prices

- **price**  
  a numeric vector: stock prices

Source

This data can be obtained from most stock websites.
visual illusions: Scintillating grid illusion and Hermann grid illusion

Description

The two most common types of grid illusions are Hermann grid illusions and Scintillating grid illusions. This function provides illustrations for both illusions.

Usage

```r
vi.grid.illusion(nrow = 8, ncol = 8, lwd = 8, cex = 3, col = "darkgray", type = c("s", "h"))
```

Arguments

- `nrow`: number of rows for the grid
- `ncol`: number of columns for the grid
- `lwd`: line width for grid lines
- `cex`: magnification for points in Scintillating grid illusions
- `col`: color for grid lines
- `type`: type of illusions: 's' for Scintillating grid illusions and 'h' for Hermann grid illusions

Details

A grid illusion is any kind of grid that deceives a person’s vision. This is actually a static image; pay attention to the intersections of the grid and there seems to be some moving points (non-existent in fact).

Value

NULL

Author(s)

Yihui Xie

See Also

- `points`, `abline`

Examples

```r
## default to be Scintillating grid illusions
vi.grid.illusion()

## set wider lines to see Hermann grid illusions
vi.grid.illusion(type = "h", lwd = 22, nrow = 5, ncol = 5, col = "white")
```
vi.lilac.chaser  Visual Illusions: Lilac Chaser

Description
Stare at the center cross for a few (say 30) seconds to experience the phenomena of the illusion.

Usage
vi.lilac.chaser(np = 16, col = "magenta", bg = "gray", p.cex = 7, c.cex = 5)

Arguments
np  number of points
col  color of points
bg  background color of the plot
p.cex  magnification of points
c.cex  magnification of the center cross

Details
Just try it out.

Value
NULL

Note
In fact, points in the original version of ‘Lilac Chaser’ are blurred, which is not implemented in this function.
