Package ‘crawl’

September 14, 2018

Type Package
Title Fit Continuous-Time Correlated Random Walk Models to Animal Movement Data
Version 2.2.1
Date 2018-09-12
 Depends R (>= 2.10)
Imports mvtnorm, Rcpp (>= 0.11.1), methods, shiny, dplyr, raster,
gdistance, rmapshaper, sp, sf, magrittr, lubridate, tibble,
purr
LinkingTo Rcpp, RcppArmadillo
Suggests ggplot2, rgdal, argosfilter, tidyR, xts, broom, doParallel
Description Fit continuous-time correlated random walk models with time indexed covariates to animal telemetry data. The model is fit using the Kalman-filter on a state space version of the continuous-time stochastic movement process.

R topics documented:
crawl-package .......................................................... 2
aic.crw .............................................................. 3
The Correlated RAndom Walk Library (I know it is not an R library, but, "crawp" did not sound as good) of R functions was designed for fitting continuous-time correlated random walk (CTCRW) models with time indexed covariates. The model is fit using the Kalman-Filter on a state space version of the continuous-time stochastic movement process.

Package: crawl
Type: Package
Version: 2.2.1
Date: September 12, 2018
License: CC0
LazyLoad: yes
Note

This software package is developed and maintained by scientists at the NOAA Fisheries Alaska Fisheries Science Center and should be considered a fundamental research communication. The recommendations and conclusions presented here are those of the authors and this software should not be construed as official communication by NMFS, NOAA, or the U.S. Dept. of Commerce. In addition, reference to trade names does not imply endorsement by the National Marine Fisheries Service, NOAA. While the best efforts have been made to insure the highest quality, tools such as this are under constant development and are subject to change.

**aic.crw**

Calculates AIC for all objects of class crwFit listed as arguments

---

**Description**

AIC, delta AIC, and Akaike weights for all models listed as arguments.

**Usage**

aic.crw(...)

**Arguments**

... a series of crwFit objects

**Details**

The function can either be executed with a series of 'crwFit' objects (see crwMLE) without the '.crwFit' suffix or the function can be called without any arguments and it will search out all 'crwFit' objects in the current workspace and produce the model selection table for all 'crwFit' objects in the workspace. Caution should be used when executing the function in this way. ALL 'crwFit' objects will be included whether or not the same locations are used! For all of the models listed as arguments (or in the workspace), AIC, delta AIC, and Akaike weights will be calculated.

**Value**

A table, sorted from lowest AIC value to highest.
Description

Using this function the user can transform the Argos diagnostic data for location error into a form usable as a covariance matrix to approximate the location error with a bivariate Gaussian distribution. The resulting data.frame should be attached back to the data with cbind to use with the crwMLE function.

Usage

argosDiag2Cov(Major, Minor, Orientation)

Arguments

Major         A vector containing the major axis information for each observation (na values are ok)
Minor         A vector containing the minor axis information for each observation (na values are ok)
Orientation   A vector containing the angle orientation of the Major axis from North (na values are ok)

Value

A data.frame with the following columns

ln.sd.x       The log standard deviation of the location error in the x coordinate
ln.sd.y       The log standard deviation of the location error in the x coordinate
rho           The correlation of the bivariate location error ellipse

Author(s)

Devin S. Johnson
as.flat

'Flattening' a list-form crwPredict object into a data.frame

Description

“Flattens” a list form crwPredict object into a flat data.frame.

Usage

as.flat(predObj)

Arguments

predObj A crwPredict object

Value

A data.frame version of a crwPredict list with columns for the state standard errors

Author(s)

Devin S. Johnson

beardedSeals Bearded Seal Location Data

Description

Bearded Seal Location Data

Format

A data frame with 27,548 observations on 3 bearded seals in Alaska:

deployid Unique animal ID
ptt Hardware ID
instr Hardware type
date_time Time of location
type Location type
quality Argos location quality
latitude Observed latitude
longitude Observed longitude
error_radius Argos error radius
error_semimajor_axis Argos error ellipse major axis length
error_semiminor_axis Argos error ellipse minor axis length
error_ellipse_orientation Argos error ellipse degree orientation

check_csv

Start a shiny app to check data stored in a .csv file for model fitting with crwMLE function.

Description

Users can start a beta version of Shiny app that allows for data checking and basic location projection.

Usage

check_csv()

cond_sim

Simulate possible path points conditioned on fit

Description

Simulates a set of possible points for a given time conditioned on fit

Usage

cond_sim(n = 500, t0, alpha0, t2, alpha2, t1, par, active = 1, inf_fac = 1, bm = 0)
Arguments

- **n**: integer specifying the number of points to return
- **t0**: time value for the first location in the segment
- **alpha0**: coordinate and velocity values for t0
- **t2**: time value for the last location in the segment
- **alpha2**: coordinate and velocity values for t2
- **t1**: time value for the current location to be simulated
- **par**: par values from the crwFit object
- **active**: numeric 1 or 0 whether the animal is moving or not (should almost always = 1)
- **inf_fac**: Variance inflation factor to increase simulation area
- **bm**: boolean whether to draw from a Brownian process

Value

matrix of coordinate and velocity values drawn

---

**crwMLE**  
*Fit Continuous-Time Correlated Random Walk Models to Animal Telemetry Data*

**Description**

The function uses the Kalman filter to estimate movement parameters in a state-space version of the continuous-time movement model. Separate models are specified for movement portion and the location error portion. Each model can depend on time indexed covariates. A “haul out” model where movement is allowed to completely stop, as well as, a random drift model can be fit with this function.

**Usage**

```r
attr

mov.model = ~1, err.model = NULL, activity = NULL, drift = FALSE, data, coord = c("x", "y"), Time.name = "time", time.scale = "hours", theta, fixPar, method = "Nelder-Mead", control = NULL, constr = list(lower = -Inf, upper = Inf), prior = NULL, need.hess = TRUE, initialsANN = list(maxit = 200), attempts = 1, ...)

Arguments

- **mov.model**: formula object specifying the time indexed covariates for movement parameters.
- **err.model**: A 2-element list of formula objects specifying the time indexed covariates for location error parameters.
- **activity**: formula object giving the covariate for the activity (i.e., stopped or fully moving) portion of the model.
drift logical indicating whether or not to include a random drift component. For most data this is usually not necessary. See northernFurSeal for an example using a drift model.

data data.frame object containing telemetry and covariate data. A 'SpatialPointsDataFrame' object from the package 'sp' or an 'sf' object from the 'sf' package with a geometry column of type sfc_POINT. 'spacetime' objects were previously accepted but no longer valid. Values for coords will be taken from the spatial data set and ignored in the arguments. Spatial data must have a valid proj4string or epsg and must NOT be in longlat.

coord A 2-vector of character values giving the names of the "X" and "Y" coordinates in data.

Time.name character indicating name of the location time column
time.scale character. Scale for conversion of POSIX time to numeric for modeling. Defaults to "hours".

theta starting values for parameter optimization.
fixPar Values of parameters which are held fixed to the given value.
method Optimization method that is passed to optim.
control Control list which is passed to optim.
constr Named list with elements lower and upper that are vectors the same length as theta giving the box constraints for the parameters

prior A function returning the log-density function of the parameter prior distribution. THIS MUST BE A FUNCTION OF ONLY THE FREE PARAMETERS. Any fixed parameters should not be included.
need.hess A logical value which decides whether or not to evaluate the Hessian for parameter standard errors

initialSANN Control list for optim when simulated annealing is used for obtaining start values. See details

attempts The number of times likelihood optimization will be attempted

... Additional arguments that are ignored.

Details

A full model specification involves 4 components: a movement model, an activity model, 2 location error models, and a drift indication. The movement model (mov.model) specifies how the movement parameters should vary over time. This is a function of specified, time-indexed, covariates. The movement parameters (sigma for velocity variation and beta for velocity autocorrelation) are both modeled with a log link as par = exp(eta), where eta is the linear predictor based on the covariates. The err.model specification is a list of 2 such models, one for “longitude” and one for “latitude” (in that order) location error. If only one location error model is given, it is used for both coordinates (parameter values as well). If drift.model is set to TRUE, then, 2 additional parameters are estimated for the drift process, a drift variance and a beta multiplier.

theta and fixPar are vectors with the appropriate number or parameters. theta contains only those parameters which are to be estimated, while fixPar contains all parameter values with NA for parameters which are to be estimated.
The data set specified by \texttt{data} must contain a numeric or \texttt{POSIXct} column which is used as the time index for analysis. The column name is specified by the \texttt{time.name} argument. If a \texttt{POSIXct} column is used it is internally converted to a numeric vector with units of \texttt{time.scale}. Also, for activity models, the sactivity covariate must be between 0 and 1 inclusive, with 0 representing complete stop of the animal (no true movement, however, location error can still occur) and 1 represent unhindered movement. The coordinate location should have \texttt{NA} where no location is recorded, but there is a change in the movement covariates.

The CTCRW models can be difficult to provide good initial values for optimization. If \texttt{initialSANN} is specified then simulated annealing is used first to obtain starting values for the specified optimization method. If simulated annealing is used first, then the returned \texttt{init} list of the \texttt{crwFit} object will be a list with the results of the simulated annealing optimization.

\textbf{Value}

A list with the following elements:

- \texttt{par} Parameter maximum likelihood estimates (including fixed parameters)
- \texttt{estPar} MLE without fixed parameters
- \texttt{se} Standard error of MLE
- \texttt{ci} 95\% confidence intervals for parameters
- \texttt{Cmat} Parameter covariance matrix
- \texttt{loglik} Maximized log-likelihood value
- \texttt{aic} Model AIC value
- \texttt{coord} Coordinate names provided for fitting
- \texttt{fixPar} Fixed parameter values provided
- \texttt{convergence} Indicator of convergence (0 = converged)
- \texttt{message} Messages given by \texttt{optim} during parameter optimization
- \texttt{activity} Model provided for stopping variable
- \texttt{drift} Logical value indicating random drift model
- \texttt{mov.model} Model description for movement component
- \texttt{err.model} Model description for location error component
- \texttt{n.par} number of parameters
- \texttt{nms} parameter names
- \texttt{n.mov} number of movement parameters
- \texttt{n.errX} number or location error parameters for "longitude" error model
- \texttt{n.errY} number or location error parameters for "latitude" error model
- \texttt{stop.mf} covariate for stop indication in stopping models
- \texttt{polar.coord} Logical indicating coordinates are polar latitude and longitude
- \texttt{init} Initial values for parameter optimization
- \texttt{data} Original data frame used to fit the model
- \texttt{lower} The lower parameter bounds
- \texttt{upper} The upper parameter bounds
- \texttt{need.hess} Logical value
- \texttt{runTime} Time used to fit model

crwN2ll -2 * log-likelihood for CTCRW models

Description
This function is designed for primary use within the crwMLE model fitting function. But, it can be accessed for advanced R and crawl users. Uses the state-space parameterization and Kalman filter method presented in Johnson et al. (2008).

Usage

crwN2ll(theta, fixPar, y, noObs, delta, mov.mf, err.mfX, err.mfY, rho = NULL, activity = NULL, n.errX, n.errY, n.mov, driftMod, prior, need.hess, constr = list(lower = -Inf, upper = Inf))

Arguments
theta parameter values.
fixPar values of parameters held fixed (contains NA for theta values).
y N by 2 matrix of coordinates with the longitude coordinate in the first column.
noObs vector with 1 for unobserved locations, and 0 for observed locations.
delta time difference to next location.
mov.mf Movement covariate data.
err.mfX longitude error covariate data.
err.mfY latitude error covariate data.
rho A vector of known correlation coefficients for the error model, typically used for modern ARGOS data.
activity Stopping covariate (= 0 if animal is not moving).
n.errX number or longitude error parameters.
n.errY number of latitude error parameters.
n.mov number or movement parameters.
driftMod Logical. indicates whether a drift model is specified.
prior Function of theta that returns the log-density of the prior
need.hess Whether or not the Hessian will need to be calculated from this call
constr Named list giving the parameter constraints

Details
This function calls compiled C++ code which can be viewed in the src directory of the crawl source package.
Value
-2 * log-likelihood value for specified CTCRW model.

Simulate a value from the posterior distribution of a CTCRW model

Description
The crwPostIS draws a set of states from the posterior distribution of a fitted CTCRW model. The draw is either conditioned on the fitted parameter values or "full" posterior draw with approximated parameter posterior

Usage
```
crwPostIS(object.sim, fullPost = TRUE, df = Inf, scale = 1, thetaSamp = NULL)
```

Arguments

- `object.sim`: A crwSimulator object from `crwSimulator`.
- `fullPost`: logical. Draw parameter values as well to simulate full posterior.
- `df`: degrees of freedom for multivariate t distribution approximation to parameter posterior.
- `scale`: Extra scaling factor for t distribution approximation.
- `thetaSamp`: If multiple parameter samples are available in object.sim, setting thetaSamp=n will use the nth sample. Defaults to the last.
Details

The crwPostIS draws a posterior sample of the track state matrices. If fullPost was set to TRUE when the object.sim was build in crwSimulator then a pseudo-posterior draw will be made by first sampling a parameter value from a multivariate t distribution which approximates the marginal posterior distribution of the parameters. The covariance matrix from the fitted model object is used to scale the MVt approximation. In addition, the factor "scale" can be used to further adjust the approximation. Further, the parameter simulations are centered on the fitted values.

To correct for the MVt approximation, the importance sampling weight is also supplied. When calculating averages of track functions for Bayes estimates one should use the importance sampling weights to calculate a weighted average (normalizing first, so the weights sum to 1).

Value

List with the following elements:

- alpha.sim.y: A matrix a simulated latitude state values
- alpha.sim.x: Matrix of simulated longitude state values
- locType: Indicates prediction types with a "p" or observation times with an "o"
- Time: Initial state covariance for latitude
- loglik: log likelihood of simulated parameter
- par: Simulated parameter value
- log.isw: non normalized log importance sampling weight

crwPredict

Predict animal locations and velocities using a fitted CTCRW model and calculate measurement error fit statistics

Description

The crwMFilter function uses a fitted model object from crwMLE to predict animal locations (with estimated uncertainty) at times in the original data set and supplemented by times in predTime. If speedEst is set to TRUE, then animal log-speed is also estimated. In addition, the measurement error shock detection filter of de Jong and Penzer (1998) is also calculated to provide a measure for outlier detection.

Usage

crwPredict(object.crwFit, predTime = NULL, return.type = "minimal", ...)

Arguments

- object.crwFit: A model object from `crwMLE`.
- predTime: vector of desired prediction times (numeric or POSIXct). Alternatively, a character vector specifying a time interval (see Details).
- return.type: character. Should be one of "minimal", "flat", "list" (see Details).
- ...: Additional arguments for testing new features

Details

The requirements for data are the same as those for fitting the model in `crwMLE`.

- ("predTime") predTime can be either passed as a separate vector of POSIXct or numeric values for all prediction times expected in the returned object. Note, previous versions of `crwPredict` would return both times specified via predTime as well as each original observed time. This is no longer the default (see return.type). If the original data were provided as a POSIXct type, then `crwPredict` can derive a sequence of regularly spaced prediction times from the original data. This is specified by providing a character string that corresponds to the by argument of the seq.POSIXt function (e.g. '1 hour', '30 mins'). `crwPredict` will round the first observed time up to the nearest unit (e.g. '1 hour' will round up to the nearest hour, '30 mins' will round up to the nearest minute) and start the sequence from there. The last observation time is truncated down to the nearest unit to specify the end time.

Value

There are three possible return types specified with return.type:

- minimal: a data.frame with a minimal set of columns: `date_time`, `mu.x`, `mu.y`, `se.mu.x`, `se.mu.y`
- flat: a data set is returned with the columns of the original data plus the state estimates, standard errors (se), and speed estimates
- list: List with the following elements:
  - originalData: A data.frame with data merged with predTime.
  - alpha.hat: Predicted state
  - Var.hat: array where Var.hat[,i] is the prediction covariance matrix for alpha.hat[,i].

Devin S. Johnson

References

**crwPredictPlot**  
*Plot CRW predicted object*

**Description**

Creates 2 types of plots of a crwPredict object: a plot of both coordinate axes with prediction intervals and a plot of just observed locations and predicted locations.

**Usage**

```r
crwPredictPlot(object, plotType = "ll", ...)
```

**Arguments**

- `object`: crwPredict object.
- `plotType`: type of plot has to be one of the following: “map” or “ll” (default).
- `...`: Further arguments passed to plotting commands.

**Value**

A plot.

See `demo(northernFurSealDemo)` for additional examples.

---

**crwSamplePar**  
*Create a weighted importance sample for posterior predictive track simulation.*

**Description**

The `crwSamplePar` function uses a fitted model object from `crwMLE` and a set of prediction times to construct a list from which `crwPostIS` will draw a sample from either the posterior distribution of the state vectors conditional on fitted parameters or a full posterior draw from an importance sample of the parameters.

**Usage**

```r
crwSamplePar(object.sim, method = "IS", size = 1000, df = Inf,  
              grid.eps = 1, crit = 2.5, scale = 1, quad.ask = T, force.quad)
```
Arguments

- **object.sim**: A simulation object from `crwSimulator`.
- **method**: Method for obtaining weights for movement parameter samples.
- **size**: Size of the parameter importance sample.
- **df**: Degrees of freedom for the t approximation to the parameter posterior.
- **grid.pts**: Grid size for `method`="quadrature".
- **crit**: Criterion for deciding "significance" of quadrature points (difference in log-likelihood).
- **scale**: Scale multiplier for the covariance matrix of the t approximation.
- **quad.ask**: Logical, for method='quadrature'. Whether or not the sampler should ask if quadrature sampling should take place. It is used to stop the sampling if the number of likelihood evaluations would be extreme.
- **force.quad**: A logical indicating whether or not to force the execution of the quadrature method for large parameter vectors.

Details

The `crwSamplePar` function uses the information in a `crwSimulator` object to create a set of weights for importance sample-resampling of parameters in a full posterior sample of parameters and locations using `crwPostIS`. This function is usually called from `crwPostIS`. The average user should have no need to call this function directly.

Value

List with the following elements:

- **x**: Longitude coordinate with NA at prediction times.
- **y**: Similar to above for latitude.
- **locType**: Indicates prediction types with a "p" or observation times with an "o".
- **p1.y**: Initial state covariance for latitude.
- **p1.x**: Initial state covariance for longitude.
- **a1.y**: Initial latitude state.
- **a1.x**: Initial longitude state.
- **n.errX**: Number of longitude error model parameters.
- **n.errY**: Number of latitude error model parameters.
- **delta**: Vector of time differences.
- **driftMod**: Logical. Indicates random drift model.
- **stopMod**: Logical. Indicated stop model fitted.
- **stop.mf**: Stop model design matrix.
- **err.mfx**: Longitude error model design matrix.
- **err.mfy**: Latitude error model design matrix.
crwSimulator

Construct a posterior simulation object for the CTCRW state vectors

description

The crwSimulator function uses a fitted model object from crwMLE and a set of prediction times to construct a list from which crwPostIS will draw a sample from either the posterior distribution of the state vectors conditional on fitted parameters or a full posterior draw from an importance sample of the parameters.

Usage

```r
crwSimulator(object.crwFit, predTime = NULL, method = "IS", parIS = 1000, df = Inf, grid.eps = 1, crit = 2.5, scale = 1, quad.ask = TRUE, force.quad)
```

Arguments

- **object.crwFit**: A model object from crwMLE.
- **predTime**: vector of additional prediction times.
- **method**: Method for obtaining weights for movement parameter samples.
- **parIS**: Size of the parameter importance sample.
The `crwSimulator` function produces a list and preprocesses the necessary components for repeated track simulation from a fitted CTCRW model from `crwMLE`. The `method` argument can be one of "IS" or "quadrature". If `method="IS"` is chosen standard importance sampling will be used to calculate the appropriate weights via t proposal with `df` degrees of freedom. If `df=Inf` (default) then a multivariate normal distribution is used to approximate the parameter posterior. If `method="quadrature"`, then a regular grid over the posterior is used to calculate the weights. The argument `grid.eps` controls the quadrature grid. The arguments are approximately the upper and lower limit in terms of standard deviations of the posterior. The default is `grid.eps`, in units of 1sd. If object `crwFit` was fitted with `crwArgoFilter`, then the returned list will also include `p.out`, which is the approximate probability that the observation is an outlier.

**Value**

List with the following elements:

- `x` Longitude coordinate with NA at prediction times
- `y` Similar to above for latitude
- `loctype` Indicates prediction types with a "p" or observation times with an "o"
- `P1.y` Initial state covariance for latitude
- `P1.x` Initial state covariance for longitude
- `a1.y` Initial latitude state
- `a1.x` Initial longitude state
- `n.errX` number of longitude error model parameters
- `n.errY` number of latitude error model parameters
- `delta` vector of time differences
- `driftMod` Logical. indicates random drift model
- `stopMod` Logical. Indicated stop model fitted
- `stop.mf` stop model design matrix
- `err.mfx` Longitude error model design matrix
- `err.mfy` Latitude error model design matrix
### crw_as_sf

Coerce to sf/sfc object

**Description**

Provides reliable conversion of "crwIS" and "crwPredict" objects into simple features objects supported in the "sf" package. Both "sf" objects with "POINT" geometry and "sfc_LINESTRING" objects are created. Coersion of "crwPredict" objects to "sfc_LINESTRING" has an option "group" argument when the "crwPredict" object includes predictions from multiple deployments. The grouping column will be used and a tibble of multiple "sf_LINESTRING" objects will be returned.

**Usage**

```r
crw_as_sf(crw_object, ftype, locType, group)
```

### Examples

#### S3 method for class 'crwIS'

```r
crw_as_sf(crw_object, ftype, locType = c("p", "o"),
          group = NULL, ...)
```

#### S3 method for class 'crwPredict'

```r
crw_as_sf(crw_object, ftype, locType = c("p", "o"),
          group = NULL, ...)
```
**Arguments**

- `crw_object`: an object of class "crwIS" or "crwPredict"
- `ftype`: character of either "POINT" or "LINESTRING" specifying the feature type
- `locType`: character vector of location points to include ("p","o")
- `group`: (optional) character specifying the column to group by for multiple LINESTRING features
- `...`: Additional arguments that are ignored

**Methods (by class)**

- `crwIS`: coerce crwIS object to sf (POINT or LINESTRING geometry)
- `crwPredict`: coerce crwPredict object to sf (POINT or LINESTRING geometry)

---

**Description**

Coerce crawl objects (crwIS and crwPredict) to tibbles

**Usage**

```r
crw_as_tibble(crw_object, ...)  
```

```r  
## S3 method for class 'crwIS'  
crw_as_tibble(crw_object, ...)  
```

```r  
## S3 method for class 'crwPredict'  
crw_as_tibble(crw_object, ...)  
```

```r  
## S3 method for class 'tbl'  
crw_as_tibble(crw_object, ...)  
```

**Arguments**

- `crw_object`: an object of class "crwIS" or "crwPredict"
- `...`: Additional arguments that are ignored

**Methods (by class)**

- `crwIS`: coerce crwIS object to tibble
- `crwPredict`: coerce crwPredict object to tibble
- `tbl`:

Josh M. London
displayPar

Display the order of parameters along with fixed values and starting values

Description

This function takes the model specification arguments to the crwMLE function and displays a table with the parameter names in the order that crwMLE will use during model fitting. This is useful for specifying values for the fixPar or theta (starting values for free parameters) arguments.

Usage

displayPar(mov.model = ~1, err.model = NULL, activity = NULL, 
drift = FALSE, data, Time.name, theta, fixPar, ...)

Arguments

mov.model formula object specifying the time indexed covariates for movement parameters.
err.model A 2-element list of formula objects specifying the time indexed covariates for location error parameters.
activity formula object giving the covariate for the stopping portion of the model.
drift logical indicating whether or not to include a random drift component.
data data.frame object containing telemetry and covariate data. A SpatialPointsDataFrame object from the package 'sp' will also be accepted.
Time.name character indicating name of the location time column
theta starting values for parameter optimization.
fixPar Values of parameters which are held fixed to the given value.
... Additional arguments (probably for testing new features.)

Value

A data frame with the following columns

ParNames The names of the parameters specified by the arguments.
fixPar The values specified by the fixPar argument for fixed values of the parameters. In model fitting, these values will remain fixed and will not be estimated.
thetaIndex This column provides the index of each element of the theta argument and to which parameter it corresponds.
thetaStart If a value is given for the theta argument it will be placed in this column and its elements will correspond to the thetaIdx column.

Devin S. Johnson
expandPred

See Also

demo(northernFurSealDemo) for example.

expandPred  Expand a time indexed data set with additional prediction times

Description

Expands a covariate data frame (or vector) that has a separate time index by inserting prediction times and duplicating the covariate values for all prediction time between subsequent data times.

Usage

expandPred(x, Time = "Time", predTime, time.col = FALSE)

Arguments

x     Data to be expanded.
Time    Either a character naming the column which contains original time values, or a numeric vector of original times
predTime prediction times to expand data
time.col Logical value indicating whether to attach the new times to the expanded data

Value

data.frame expanded by predTime

Author(s)

Devin S. Johnson

Examples

#library(crawl)
origTime <- c(1:10)
x <- cbind(rnorm(10), c(21:30))
predTime <- seq(1,10, by=0.25)
expandPred(x, Time=origTime, predTime, time.col=TRUE)
fillCols

Fill missing values in data set (or matrix) columns for which there is a single unique value

Description

Looks for columns in a data set that have a single unique non-missing value and fills in all NA with that value

Usage

fillCols(data)

Arguments

data data.frame

Value

data.frame

Author(s)

Devin S. Johnson

Examples

#library(crawl)
data1 <- data.frame(constVals=rep(c(1,NA),5), vals=1:10)
data1[5,2] <- NA
data1
data2 <- fillCols(data1)
data2

**fix_path**

*Project path away from restricted areas*

**Description**
Corrects a path so that it does not travel through a restricted area.

**Usage**
```r
fix_path(crw_object, vector_mask, crwFit)
```

**Arguments**
- `crw_object` Coordinate locations for the path. Can be one of the following classes: (1) `'crwIS'` object from the `crwPostIS` function
- `vector_mask` an `sf` polygon object that defines the restricted area
- `crwFit` crwFit object that was used to generate the crw_object

**Value**
a new crw_object (of type crwIS)

**fix_segments**

*Identify segments of a path that cross a restricted area*

**Description**
This function takes a crw_object (crwIS only for now) and an `sf` polygon object that defines the restricted area and identifies each segment of the path that crosses the restricted area. Each segment begins and ends with a coordinate that is outside the restricted area.

**Usage**
```r
fix_segments(crw_object, vector_mask, crwFit)
```

**Arguments**
- `crw_object` Coordinate locations for the path. Can be one of the following classes: (1) `'crwIS'` object from the `crwPostIS` function
- `vector_mask` an `sf` polygon object that defines the restricted area
- `crwFit` crwFit object that was used to generate the crw_object

**Value**
a tibble with each record identifying the segments and pertinent values
get_mask_segments

flatten

"Flattening" a list-form crwPredict object into a data.frame

Description

“Flattens” a list form crwPredict object into a flat data.frame.

Usage

flatten(predObj)

Arguments

- predObj: A crwPredict object

Value

A data.frame version of a crwPredict list with columns for the state standard errors

Author(s)

Devin S. Johnson

get_mask_segments

Identify segments of a path that cross through a restricted area

Description

This function is used to identify sections of a path that pass through a restricted area (e.g. for marine mammals or fish, a land mask). The CTCRW model in crawl cannot actively steer paths away from land. So, this function will identify path segments from the unrestrained path that pass through these areas. If the path/points end within the land area, those records will be removed. The user can then use this information to adjust the path as desired.

Usage

generate_mask_segments(crw_object, vector_mask)

Arguments

- crw_object: A crwIS object from the crawl package
- vector_mask: A sf object from sf package that indicates restricted areas as a polygon feature.
Value

A data frame with each row associated with each section of the path that crosses a restricted area. The columns provide the start and end row indices of xy where the section occurs and the previous and post locations that are in unrestricted space.

harborSeal Harbor seal relocation data set used in Johnson et al. (2008)

Description

Harbor seal relocation data set used in Johnson et al. (2008)

Format

A data frame with 7059 observations on the following 5 variables.

- **Time** a numeric vector.
- **latitude** a numeric vector.
- **longitude** a numeric vector.
- **DryTime** a numeric vector.
- **Argos_loc_class** a factor with levels 0 1 2 3 A B.

intToPOSIX

Reverse as.numeric command that is performed on a vector of type POSIXct

Description
Takes integer value produced by as.numeric(x), where x is a POSIXct vector and returns it to a POSIXct vector

Usage
intToPOSIX(timeVector, tz = "GMT")

Arguments
- timeVector: A vector of integers produced by as.numeric applied to a POSIXct vector
- tz: Time zone of the vector (see as.POSIXct).

Value
POSIXct vector

Note
There is no check that as.numeric applied to a POSIX vector produced timeVector. So, caution is required in using this function. It was included simply because I have found it useful

Author(s)
Devin S. Johnson

Examples

```r
#library(crawl)
timeVector <- as.numeric(Sys.time())
timeVector
intToPOSIX(timeVector, tz="")
```
**mergeTrackStop**

*Merge a location data set with a dry time (or other stopping) covariate*

**Description**

The function merges a location data set with a stopping variable data set.

**Usage**

```r
mergeTrackStop(data, stopData, Time.name = "Time", interp = c("zeros", "ma0"), win = 2, constCol)
```

**Arguments**

- `data`: Location data.
- `stopData`: Stopping variable data set.
- `Time.name`: Character naming time index variable in both data sets.
- `interp`: Method of interpolation.
- `win`: Window for "ma0" interpolation method.
- `constCol`: Columns in `data` for which the user would like to be constant, such as id or sex.

**Details**

Simply merges the data frames and interpolates based on the chosen method. Both data frames have to use the same name for the time variable. Also contains `stopType` which = "o" if observed or "p" for interpolated.

The merged data is truncated to the first and last time in the location data set. Missing values in the stopping variable data set can be interpolated by replacing them with zeros (full movement) or first replacing with zeros then using a moving average to smooth the data. Only the missing values are then replace with this smoothed data. This allows a smooth transition to full movement.

**Value**

Merged data frame with new column from `stopData`. Missing values in the stopping variable will be interpolated.

northernFurSeal

Examples

```r
track <- data.frame(TimeVar=sort(runif(20,0,20)), x=1:20, y=20:1)
track
stopData <- data.frame(TimeVar=0:29, stopVar=round(runif(30)))
stopData
mergeTrackStop(track, stopData, Time.name="TimeVar")
```

northernFurSeal Northern fur seal pup relocation data set used in Johnson et al. (2008)

Description

Northern fur seal pup relocation data set used in Johnson et al. (2008)

Format

A data frame with 795 observations on the following 4 variables:

- GMT  A POSIX time vector
- loc_class  a factor with levels 3 2 1 0 A.
- lat  a numeric vector. Latitude for the locations
- long  a numeric vector. Longitude for the locations

tidy_crwFit

**tidy_crwFit**  
tidy-like method for crwFit object

---

**Description**

this function mimics the approach taken by broom::tidy to present model output parameters in a tidy, data frame structure.

**Usage**

```r
 tidy_crwFit(fit)
```

**Arguments**

- **fit**  
crwFit object from crawl::crwMLE
