<td>Extending ‘dendrogram’ Functionality in R</td>
</tr>
<tr>
<td>Version</td>
<td>1.10.0</td>
</tr>
<tr>
<td>Date</td>
<td>2019-03-15</td>
</tr>
<tr>
<td>Description</td>
<td>Offers a set of functions for extending 'dendrogram' objects in R, letting you visualize and compare trees of 'hierarchical clusterings'. You can (1) Adjust a tree's graphical parameters - the color, size, type, etc of its branches, nodes and labels. (2) Visually and statistically compare different 'dendrograms' to one another.</td>

Functions for extending dendrogram objects

Description

Functions for extending dendrogram objects

See Also

dendrogram, hclust in stats package.
all.equal.dendrogram  Global Comparison of two (or more) dendrograms

Description

This function makes a global comparison of two or more dendrograms trees.

The function can get two dendlist objects and compare them using all.equal.list. If a dendlist is in only "target" (and not "current"), it will go through the dendlist and compare all of the dendrograms within it to one another.

Usage

## S3 method for class 'equal.dendrogram'
all(target, current, use.edge.length = TRUE,
    use.tip.label.order = FALSE, use.tip.label = TRUE, use.topology = TRUE,
    tolerance = .Machine$double.eps^0.5, scale = NULL, ...)

Arguments

- target: an object of type dendrogram or dendlist
- current: an object of type dendrogram
- use.edge.length: logical (TRUE). If to check branches' heights.
- use.tip.label.order: logical (FALSE). If to check labels are in the same and in identical order
- use.tip.label: logical (TRUE). If to check that labels are the same (regardless of order)
- use.topology: logical (TRUE). If to check the existence of distinct edges
- tolerance: the numeric tolerance used to compare the branch lengths.
- scale: a positive number (NULL as default), comparison of branch height is made after scaling (i.e., dividing) them by this number.
- ...: Ignored.

Value

Either TRUE (NULL for attr.all.equal) or a vector of mode "character" describing the differences between target and current.

all.equal, all.equal.phylo, identical
all_couple_rotations_at_k

Examples

```r
## Not run:

set.seed(23235)
ss <- sample(1:150, 10)
dend1 <- iris[ss,-5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[ss,-5] %>% dist %>% hclust("single") %>% as.dendrogram
dend3 <- iris[ss,-5] %>% dist %>% hclust("ave") %>% as.dendrogram
dend4 <- iris[ss,-5] %>% dist %>% hclust("centroid") %>% as.dendrogram
# cutree(dend1)
all.equal(dend1, dend1)
all.equal(dend1, dend2)
all.equal(dend1, dend2, use.edge.length = FALSE)
all.equal(dend1, dend2, use.edge.length = FALSE, use.topology = FALSE)
all.equal(dend2, dend4, use.edge.length = TRUE)
all.equal(dend2, dend4, use.edge.length = FALSE)
all.equal(dendlist(dend1, dend2, dend3, dend4))
all.equal(dendlist(dend1, dend2, dend3, dend4), use.edge.length = FALSE)
all.equal(dendlist(dend1, dend1, dend1))

## End(Not run)
```

all_couple_rotations_at_k

*Rotate tree branches for k*

**Description**

Given a tree and a k number of clusters, the tree is rotated so that the extra clusters added from k-1 to k clusters are flipped.

This is useful for finding good trees for a tanglegram.

**Usage**

`all_couple_rotations_at_k(dend, k, dend_heights_per_k, ...)`

**Arguments**

- `dend` a dendrogram object
- `k` integer scalar with the number of clusters the tree should be cut into.
- `dend_heights_per_k` a named vector that resulted from running `heights_per_k.dendrogram`. When running the function many times, supplying this object will help improve the running time if using the `cutree.dendrogram` method.
all_unique

... not used

Value
A list with dendrogram objects with all the possible rotations for k clusters (beyond the k-1 clusters!).

See Also
tanglegram, match_order_by_labels, entanglement, flip_leaves.

Examples

```r
## Not run:
dend1 <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram
dend2 <- all_couple_rotations_at_k(dend1, k=2)[[2]]
tanglegram(dend1,dend2)
entanglement(dend1,dend2, L = 2) # 0.5

dend2 <- all_couple_rotations_at_k(dend1, k=3)[[2]]
tanglegram(dend1,dend2)
entanglement(dend1,dend2, L = 2) # 0.4

dend2 <- all_couple_rotations_at_k(dend1, k=4)[[2]]
tanglegram(dend1,dend2)
entanglement(dend1,dend2, L = 2) # 0.05

## End(Not run)
```

---

all_unique Check if all the elements in a vector are unique

Description
Checks if all the elements in a vector are unique

Usage

```r
all_unique(x, ...)
```

Arguments

- `x` a vector
- `...` ignored.

Value

logical (are all the elements in the vector unique)
as.dendlist

Source

See Also
unique

Examples

all_unique(c(1:5, 1,1))
all_unique(c(1,1,2))
all_unique(c(1,1,2, 3,3,3,3))
all_unique(c(1,3,2))
all_unique(c(1:10))

as.dendlist Try to coerce something into a dendlist

Description
It removes stuff that are not dendrogram/dendlist and turns what is left into a dendlist

Usage
as.dendlist(x, ...)

Arguments
x a list with several dendrogram/hclust/phylo or dendlist objects and other junk that should be omitted.
... NOT USED

Value
A list of class dendlist where each item is a dendrogram

Examples

## Not run:
dend <- iris[, -5] %>% dist %>% hclust %>% as.dendrogram
dend2 <- iris[, -5] %>% dist %>% hclust(method = "single") %>% as.dendrogram
x = list(dend, 1, dend2)
as.phylo.dendrogram

as.dendlist(x)

## End(Not run)

as.phylo.dendrogram  Convert a dendrogram into phylo

Description

Based on as.hclust.dendrogram with as.phylo.hclust

In the future I hope a more direct link will be made.

Usage

as.phylo.dendrogram(x, ...)

Arguments

x  a dendrogram
...
... ignored.

Value

A phylo class object

See Also

as.dendrogram, as.hclust, as.phylo

Examples

## Not run:

library(dendextend)
library(ape)
dend <- iris[,3:5] %>% dist %>% hclust %>% as.dendrogram
dend2 <- as.phylo(dend)
plot(dend2, type = "fan")

# Also possible to with ggplot2 :)

library(dendextend)
library(ggplot2)
library(ggdendro)
dend <- iris[,3:5] %>% dist %>% hclust %>% as.dendrogram
# Rectangular lines
assign_dendextend_options

Populates dendextend functions into dendextend_options

Description
Populates dendextend functions into dendextend_options

Usage
assign_dendextend_options()

assign_values_to_branches_edgePar

Assign values to edgePar of dendrogram’s branches

Description
Go through the dendrogram branches and updates the values inside its edgePar
If the value has Inf then the value in edgePar will not be changed.

Usage
assign_values_to_branches_edgePar(dend, value, edgePar, skip_leaves = FALSE, warn = dendextend_options("warn"), ...)
Arguments

dend a dendrogram object
value a new value scalar for the edgePar attribute.
edgePar a character indicating the value inside edgePar to adjust. Can be either "col", "lty", or "lwd".
skip_leaves logical (FALSE) - should the leaves be skipped/ignored?
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

Value

A dendrogram, after adjusting the edgePar attribute in all of its branches,

See Also

get_root_branches_attr

Examples

# This failed before - now it works fine. (thanks to Martin Maechler)
dend <- 1:2 %>% dist %>% hclust %>% as.dendrogram
dend %>% set("branches_lty", 1:2) %>%
  set("branches_col", c("topbranch_never_plots", "black", "orange")) %>%
plot

## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram
plot(dend)
dend <- assign_values_to_branches_edgePar(dend=dend, value = 2, edgePar = "lwd")
plot(dend)
dend <- assign_values_to_branches_edgePar(dend=dend, value = 2, edgePar = "col")
plot(dend)
dend <- assign_values_to_branches_edgePar(dend=dend, value = "orange", edgePar = "col")
plot(dend)
dend2 <- assign_values_to_branches_edgePar(dend=dend, value = 2, edgePar = "lty")
plot(dend2)
dend2 %>% unclass %>% str

## End(Not run)
assign_values_to_leaves_edgePar

Assign values to edgePar of dendrogram’s leaves

Description

Go through the dendrogram leaves and updates the values inside its edgePar.
If the value has Inf then the value in edgePar will not be changed.

Usage

assign_values_to_leaves_edgePar(dend, value, edgePar,
    warn = dendextend_options("warn"), ...)

Arguments

dend a dendrogram object
value a new value vector for the edgePar attribute. It should be the same length as the number of leaves in the tree. If not, it will recycle the value and issue a warning.
edgePar the value inside edgePar to adjust.
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
... not used

Value

A dendrogram, after adjusting the edgePar attribute in all of its leaves,

See Also

get_leaves_attr, linkassign_values_to_leaves_nodePar

Examples

## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust("ave") %>% as.dendrogram
plot(dend)
dend <- assign_values_to_leaves_edgePar(dend=dend, value = c(3,2), edgePar = "col")
plot(dend)
dend <- assign_values_to_leaves_edgePar(dend=dend, value = c(3,2), edgePar = "lwd")
assign_values_to_leaves_nodePar

Assign values to nodePar of dendrogram's leaves

Description
Go through the dendrogram leaves and updates the values inside its nodePar.
If the value has Inf then the value in edgePar will not be changed.

Usage
assign_values_to_leaves_nodePar(dend, value, nodePar, warn = dendextend_options("warn"), ...)

Arguments
dend a dendrogram object
value a new value vector for the nodePar attribute. It should be the same length as the number of leaves in the tree. If not, it will recycle the value and issue a warning.
nodePar the value inside nodePar to adjust.
warm logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
... not used

Value
A dendrogram, after adjusting the nodePar attribute in all of its leaves.

See Also
get_leaves_attr

plot(dend)
dend <- assign_values_to_leaves_edgePar(dend=dend, value = c(3,2), edgePar = "lty")
plot(dend)

get_leaves_attr(dend, "edgePar", simplify=FALSE)

## End(Not run)
assign_values_to_nodes_nodePar

Examples

## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust("ave") %>% as.dendrogram

# reproduces "labels_colors<-"
# although it does force us to run through the tree twice,
# hence "labels_colors<-" is better...
plot(dend)
dend <- assign_values_to_leaves_nodePar(dend=dend, value = c(3,2), nodePar = "lab.col")
plot(dend)

dend <- assign_values_to_leaves_nodePar(dend, 1, "pch")
plot(dend)
# fix the annoying pch=1:
dend <- assign_values_to_leaves_nodePar(dend, NA, "pch")
plot(dend)
# adjust the cex:
dend <- assign_values_to_leaves_nodePar(dend, 19, "pch")
dend <- assign_values_to_leaves_nodePar(dend, 2, "lab.cex")
plot(dend)

str(unclass(dend))

get_leaves_attr(dend, "nodePar", simplify=FALSE)

## End(Not run)

assign_values_to_nodes_nodePar

Assign values to nodePar of dendrogram's nodes

Description

Go through the dendrogram nodes and updates the values inside its nodePar

If the value has Inf then the value in edgePar will not be changed.

Usage

assign_values_to_nodes_nodePar(dend, value, nodePar = c("pch", "cex", "col", "xpd", "bg"), warn = dendextend_options("warn"), ...)

Arguments

dend a dendrogram object
assign_values_to_nodes_nodePar

value

A new value vector for the nodePar attribute. It should be the same length as the number of nodes in the tree. If not, it will recycle the value and issue a warning.

depPar

The value inside nodePar to adjust. This may contain components named pch, cex, col, xpd, and/or bg.

warn

Logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

Value

A dendrogram, after adjusting the nodePar attribute in all of its nodes,

See Also

gt_leaves_attr, assign_values_to_leaves_nodePar

Examples

## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust("ave") %>% as.dendrogram

# reproduces "labels_colors<-"
# although it does force us to run through the tree twice,
# hence "labels_colors<-" is better...
plot(dend)
dend2 <- dend %>%
    assign_values_to_nodes_nodePar(value = 19, nodePar = "pch") %>%
    assign_values_to_nodes_nodePar(value = c(1,2), nodePar = "cex") %>%
    assign_values_to_nodes_nodePar(value = c(2,1), nodePar = "col")
plot(dend2)

### Making sure this works for NA with character.

dend %>%
    assign_values_to_nodes_nodePar(value = 19, nodePar = "pch") %>%
    assign_values_to_nodes_nodePar(value = c("red", NA), nodePar = "col") -> dend2
plot(dend2)

## End(Not run)
as_hclust_fixed

Convert dendrogram Objects to Class hclust

Description

Convert dendrogram Objects to Class hclust while preserving the call/method/dist.method values of the original hclust object (hc)

Usage

as_hclust_fixed(x, hc, ...)

Arguments

x
  any object which has an as.hclust method. (mostly used for dendrogram)

hc
  an old hclust object from which to re-use the call/method/dist.method values

...  
  passed to as.hclust

Value

An hclust object (from a dendrogram) with the original hclust call/method/dist.method values

See Also

as.hclust

Examples

hc <- hclust(dist(USArrests[,1:3]), "ave")
dend <- as.dendrogram(hc)

as.hclust(dend)
as_hclust_fixed(dend, hc)

bakers_gamma_for_2_k_matrix

Bakers Gamma for two k matrices

Description

Bakers Gamma for two k matrices

Usage

bakers_gamma_for_2_k_matrix(k_matrix_dend1, k_matrix_dend2, to_plot = FALSE)
Arguments

- **k_matrix_dend1**: a matrix of k cluster groupings from a dendrogram
- **k_matrix_dend2**: a (second) matrix of k cluster groupings from a dendrogram
- **to_plot**: logical (FALSE). Should a scatterplot be plotted, showing the correlation between the lowest shared branch between two items in the two compared trees.

... not used

Value

Baker’s Gamma coefficient.

See Also

- `cor_bakers_gamma`

Description

Bk is the calculation of Fowlkes-Mallows index for a series of k cuts for two dendrograms.

Usage

Bk(tree1, tree2, k, include_EV = TRUE, warn = dendextend_options("warn"), ...)

Arguments

- **tree1**: a dendrogram/hclust/phylo object.
- **tree2**: a dendrogram/hclust/phylo object.
- **k**: an integer scalar or vector with the desired number of cluster groups. If missing - the Bk will be calculated for a default k range of 2:(nleaves-1). No point in checking k=1/k=n, since both will give Bk=1.
- **include_EV**: logical (TRUE). Should we calculate expectancy and variance of the FM Index under null hypothesis of no relation between the clusterings? If TRUE (Default) - then the FM_index_R function, else (FALSE) we use the (faster) FM_index_profdpm function.
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

... Ignored (passed to FM_index_R/FM_index_profdpm).
Details

From Wikipedia:

Fowlkes-Mallows index (see references) is an external evaluation method that is used to determine the similarity between two clusterings (clusters obtained after a clustering algorithm). This measure of similarity could be either between two hierarchical clusterings or a clustering and a benchmark classification. A higher the value for the Fowlkes-Mallows index indicates a greater similarity between the clusters and the benchmark classifications.

Value

A list (of k’s length) of Fowlkes-Mallows index between two dendrogram for a scalar/vector of k values. The names of the lists’ items is the k for which it was calculated.

```
Bk_permutations

Bk permutation - Calculating Fowlkes-Mallows Index for two dendrogram

Description

Bk is the calculation of Fowlkes-Mallows index for a series of k cuts for two dendrograms.

Bk permutation calculates the Bk under the null hypothesis of no similarity between the two trees by randomly shuffling the labels of the two trees and calculating their Bk.

Usage

Bk_permutations(tree1, tree2, k, R = 1000,
warn = dendextend_options("warn"), ...)

Arguments

tree1 a dendrogram/hclust/phylo object.
tree2 a dendrogram/hclust/phylo object.
k an integer scalar or vector with the desired number of cluster groups. If missing - the Bk will be calculated for a default k range of 2:(nleaves-1). No point in checking k=1/k=n, since both will give Bk=1.
R integer (Default is 1000). The number of Bk permutation to perform for each k.
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. If set to TRUE, extra checks are made to verify that the two clusters have the same size and the same labels.
... Ignored (passed to FM_index_R/FM_index_profdpm).
Details

From Wikipedia:

Fowlkes-Mallows index (see references) is an external evaluation method that is used to determine
the similarity between two clusterings (clusters obtained after a clustering algorithm). This measure
of similarity could be either between two hierarchical clusterings or a clustering and a benchmark
classification. A higher the value for the Fowlkes-Mallows index indicates a greater similarity
between the clusters and the benchmark classifications.

Value

A list (of the length of k’s), where each element of the list has R (number of permutations) calcula-
tions of Fowlkes-Mallows index between two dendrogram after having their labels shuffled.
The names of the lists’ items is the k for which it was calculated.

## Not run:

```r
set.seed(23235)
ss <- TRUE # sample(1:150, 10 )
hc1 <- hclust(dist(iris[ss,-5]), "com")
hc2 <- hclust(dist(iris[ss,-5]), "single")
# tree1 <- as.treegram(hc1)
# tree2 <- as.treegram(hc2)
# cutree(tree1)

some_Bk <- Bk(hc1, hc2, k = 20)
some_Bk_permu <- Bk_permutations(hc1, hc2, k = 20)

# we can see that the Bk is much higher than the permutation Bks:
plot(x=rep(1,1000), y= some_Bk_permu[[1]],
main = "Bk distribution under H0",
ylim = c(0,1))
points(1, y= some_Bk, pch = 19, col = 2 )
```

## End(Not run)
Bk_plot

Bk plot - plotting the Fowlkes-Mallows Index of two dendrogram for various k’s

Description

Bk is the calculation of Fowlkes-Mallows index for a series of k cuts for two dendrograms. A Bk plot is simply a scatter plot of Bk versus k. This plot helps in identifying the similarity between two dendrograms in different levels of k (number of clusters).

Usage

```r
Bk_plot(tree1, tree2, k, add_E = TRUE, rejection_line_asymptotic = TRUE,
        rejection_line_permutation = FALSE, R = 1000, k_permutation,
        conf.level = 0.95, p.adjust.methods = c("none", "bonferroni"),
        col_line_Bk = 1, col_line_asymptotic = 2, col_line_permutation = 4,
        warn = dendextend_options("warn"), main = "Bk plot",
        xlab = "k (number of clusters)", ylab = "Bk (Fowlkes-Mallows Index)",
        xlim, ylim = c(0, 1), try_cutree_hclust = TRUE, 
)
```

Arguments

- **tree1**: a dendrogram/hclust/phylo object.
- **tree2**: a dendrogram/hclust/phylo object.
- **k**: an integer scalar or vector with the desired number of cluster groups. If missing - the Bk will be calculated for a default k range of 2:(nleaves-1). No point in checking k=1/k=n, since both will give Bk=1.
- **add_E**: logical (TRUE). Should we add a line of the Expected Bk value for each k, under the null hypothesis of no relation between the clusterings?
- **rejection_line_asymptotic**: logical (TRUE). Should we add a line of the one sided rejection region based on the asymptotic distribution of Bk values, for each k, under the null hypothesis of no relation between the clusterings?
- **rejection_line_permutation**: logical (FALSE). Should we add a line of the one sided rejection region based on the asymptotic distribution of Bk values, for each k, under the null hypothesis of no relation between the clusterings?
- **R**: integer (Default is 1000). The number of Bk permutation to perform for each k. Applicable only if rejection_line_permutation is TRUE.
- **k_permutation**: the k’s to be used for permutation (sometimes we might be only interested in some k’s and it is not important to run the simulation for all possible ks). If missing - k itself will be used.
- **conf_level**: the level of one sided confidence interval used for creation of the rejection lines.
p.adjust.methods

A character scalar of either "none" (default), or "bonferroni". This controls the multiple correction method to use for the critical rejection values. Currently only the Bonferroni method is implemented (based on the number of different k values).

col_line_Bk

The color of the Bk line.

col_line_asymptotic

The color of the rejection asymptotic Bk line.

col_line_permutation

The color of the rejection asymptotic Bk line.

warn

Logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. If set to TRUE, extra checks are made to verify that the two clusters have the same size and the same labels.

main

Passed to plot.

xlab

Passed to plot.

ylab

Passed to plot.

xlim

Passed to plot. If missign, xlim is from 2 to nleaves-1

ylim

Passed to plot.

try_cutree_hclust

Logical (TRUE). Since cutree for hclust is MUCH faster than for dendrogram - Bk.plot will first try to change the dendrogram into an hclust object. If it will fail (for example, with unbranched trees), it will continue using the cutree.dendrogram functions. If try_cutree_hclust=FALSE, it will force to use cutree.dendrogram and not cutree.hclust.

... Ignored.

Details

From Wikipedia:

Fowlkes-Mallows index (see references) is an external evaluation method that is used to determine the similarity between two clusterings (clusters obtained after a clustering algorithm). This measure of similarity could be either between two hierarchical clusterings or a clustering and a benchmark classification. A higher the value for the Fowlkes-Mallows index indicates a greater similarity between the clusters and the benchmark classifications.

The default Bk plot comes with a line with dots (type "b") of the Bk values. Also with a fragmented (lty=2) line (of the same color) of the expected Bk line under H0, And a solid red line of the upper critical Bk values for rejection.

Value

After plotting the Bk plot. Returns (invisible) the output of the elements used for constructing the plot: The Bk values, Bk permutations (if used), Bk theoratical values, etc.
References

FM_index, Bk, Bk_permutations

Examples

```r
set.seed(23235)
ss <- TRUE # sample(1:150, 10 )
hc1 <- hclust(dist(iris[ss,-5]), "com")
hc2 <- hclust(dist(iris[ss,-5]), "single")
# tree1 <- as.treerogram(hc1)
# tree2 <- as.treerogram(hc2)
# cutree(tree1)

Bk_plot(hc1, hc2, k = 2:20, xlim = c(2,149))
Bk_plot(hc1, hc2)
Bk_plot(hc1, hc2, k = 3)
Bk_plot(hc1, hc2, k = 3:10)
Bk_plot(hc1, hc2)
Bk_plot(hc1, hc2,p.adjust.methods="bonferroni") # higher rejection lines

# this one can take a bit of time:
Bk_plot(hc1, hc2, rejection_line_permutation=TRUE, k_permutation = c(2,4,6,8,10,20,30,40,50), R= 100)
# we can see that the permutation line is VERY close to the asymptotic line.
# This is great since it means one can often use the asymptotic results
# Without having to do many simulations.

# works just as well for dendrograms:
dend1 <- as.dendrogram(hc1)
dend2 <- as.dendrogram(hc2)
Bk_plot(dend1, dend2, k = 2:3, try_cutree_hclust = FALSE) # slower than hclust, but works...
Bk_plot(hc1, dend2, k = 2:3, try_cutree_hclust = FALSE) # slower than hclust, but works...
Bk_plot(dend1, dend1, k = 2:3, try_cutree_hclust = TRUE) # slower than hclust, but works...
Bk_plot(hc1, hc1, k = 2:3) # slower than hclust, but works...
# for some reason it can't turn dend2 back to hclust :
# a= Bk_plot(hc1, hc2, k = 2:3, try_cutree_hclust = TRUE) # slower than hclust, but works...

hc1_mixed <- as.hclust(sample(as.dendrogram(hc1)))
Bk_plot(tree1=hc1, tree2=hc1_mixed,
       add_E=FALSE,
       rejection_line_permutation=TRUE, k_permutation = c(2,4,6,8,10,20,30,40,50), R= 100)
```
### branches_attr_by_clusters

**Change col/lwd/lty of branches based on clusters**

### Description

The user supplies a dend, a vector of clusters, and what to modify (and how).

And the function returns a dendrogram with branches col/lwd/lty accordingly. (the function assumes unique labels)

### Usage

```r
branches_attr_by_clusters(dend, clusters, values, attr = c("col", "lwd", "lty"), branches_changed_have_which_labels = c("any", "all"), ...)
```

### Arguments

- **dend**
  - a dendrogram dend

- **clusters**
  - an integer vector of clusters. This HAS to be of the same length as the number of leaves. Items that belong to no cluster should get the value 0. The vector should be of the same order as that of the labels in the dendrogram. If you create the clusters from something like cutree you would first need to use order.dendrogram on it, before using it in the function.

- **values**
  - the attributes to use for non 0 values. This should be of the same length as the number of unique non-0 clusters. If it is shorter, it is recycled. OR, this can also be of the same length as the number of leaves in the tree In which case, the values will be aggregated (i.e.: tapply), to match the number of clusters. The first value of each cluster will be used as the main value.

- **attr**
  - a character with one of the following values: col/lwd/lty

- **branches_changed_have_which_labels**
  - character with either "any" (default) or "all". Indicates how the branches should be updated.

- **...**
  - ignored.

### Details

This is probably NOT a very fast implementation of the function, but it works.

This function was designed to enable the manipulation (mainly coloring) of branches, based on the results from the cutreeDynamic function.
Value

A dendrogram with modified branches (col/lwd/lt).

See Also

branches_attr_by_labels, get_leaves_attr, nnodes, nleaves, cutreeDynamic, plotDendroAndColors

Examples

### Not run:

```r
# Getting the hc object
iris_dist <- iris[, -5]  # dist
hc <- iris_dist %>% hclust
# This is how it looks without any colors:
dend <- as.dendrogram(hc)
plot(dend)

# Both functions give the same outcome
# options 1:
dend %>% set("branches_k_color", k = 4) %>% plot
# options 2:
clusters <- cutree(dend, 4)[order.dendrogram(dend)]
dend %>% branches_attr_by_clusters(clusters) %>% plot

# and the second option is much slower:
system.time(set(dend, "branches_k_color", k = 4))  # 0.26 sec
system.time(branches_attr_by_clusters(dend, clusters))  # 1.61 sec
# BUT, it also allows us to do more flexible things!
```

# Plotting dynamicTreeCut

```r
# let's get the clusters
library(dynamicTreeCut)
clusters <- cutreeDynamic(hc, distM = as.matrix(iris_dist))
# we need to sort them to the order of the dendrogram:
clusters <- clusters[order.dendrogram(dend)]

# get some functions:
library(dendextendRcpp)
library(colorspace)
no0_unique <- function(x) {
  u_x <- unique(x)
  u_x[u_x != 0]
}

clusters_numbers <- no0_unique(clusters)
n_clusters <- length(clusters_numbers)
cols <- rainbow_hcl(n_clusters)
```
branches_attr_by_labels

Change col/lwd/lty of branches matching labels condition

Description

The user supplies a dend, labels, and type of condition (all/any), and TF_values. The function returns a dendrogram with branches col/lwd/lty accordingly.

Usage

```r
branches_attr_by_labels(dend, labels, TF_values = c(2, Inf), attr = c("col", "lwd", "lty"), type = c("all", "any"), ...)
```

Arguments

dend
a dendrogram dend

labels
a character vector of labels from the tree

TF_values
a two-dimensional vector with the TF_values to use in case a branch fulfills the condition (TRUE) and in the case that it does not (FALSE). Defaults are 2/Inf for col, lwd and lty. (so it will insert the first value, and will not change all the FALSE cases)

attr
a character with one of the following values: col/lwd/lty
branches_attr_by_labels

- **type**
  - A character vector of either "all" or "any", indicating which of the branches should be painted: ones that all of their labels belong to the supplied labels, or also ones that even some of their labels are included in the labels vector.

- **Value**
  - A dendrogram with modified branches (col/lwd/lty).

- **See Also**
  - `noded_with_condition`, `get_leaves_attr`, `nnodes`, `nleaves`

- **Examples**

  ```r
  # Not run:
  library(dendextend)

  set.seed(23235)
  ss <- sample(1:150, 10)

  # Getting the dend dend
  dend <- iris[ss,-5] %>% dist %>% hclust %>% as.dendrogram
  dend %>% plot
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29")) %>% plot
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29"), "all") %>% plot # the same as above
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29"), "any") %>% plot
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29"), "any", "col", c("blue", "red")) %>% plot
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29"), "any", "lwd", c(4,1)) %>% plot
  dend %>% branches_attr_by_labels(c("123", "126", "23", "29"), "any", "lty", c(2,1)) %>% plot
  # End(Not run)
branches_attr_by_lists

Change col/lwd/lty of branches from the root down to clusters defined by list of labels of respective members

Description

The user supplies a dend, lists, and type of condition (all/any), and TF_values. And the function returns a dendrogram with branches col/lwd/lty accordingly.

Usage

`branches_attr_by_lists(dend, lists, TF_values = c(2, 1), attr = c("col", "lwd", "lty"), ...)`

Arguments

dend: a dendrogram dend

lists: a list where each element contains the labels of members in selected nodes down to which the branches shall be adapted

TF_values: a two-dimensional vector with the TF_values to use in case a branch fulfills the condition (TRUE) and in the case that it does not (FALSE). Defaults are 2/1 for col, lwd, and lty. (so it will insert the first value, and will not change all the FALSE cases)

attr: a character with one of the following values: col/lwd/lty

... ignored.

Value

A dendrogram with modified branches (col/lwd/lty).

See Also

`branches_attr_by_labels`

Examples

```r
## Not run:

library(dendextend)

set.seed(23235)
sample(1:150, 10)

# Getting the dend dend
dend <- iris[ss,-5] %>% dist %>% hclust %>% as.dendrogram
dend %>% plot
```
# define a list of nodes
L <- list(c("109", "123", "126", "145"), c("29", c("59", "67", "97")))
dend %>%
  branches_attr_by_lists(L) %>%
  plot

# choose different color, and also change lwd and lty
dend %>%
  branches_attr_by_lists(L, TF_value = "blue") %>%
  branches_attr_by_lists(L, attr = "lwd", TF_value = 4) %>%
  branches_attr_by_lists(L, attr = "lty", TF_value = 3) %>%
  plot

## End(Not run)

circlize_dendrogram  Plot a circlized dendrograms

Description

Plot a circlized dendrograms using the circlize package (must be installed for the function to work).
This type of plot is also sometimes called fan tree plot (although the name fan-plot is also used for a
different plot in time series analysis), radial tree plot, polar tree plot, circular tree plot, and probably
other names as well.

An advantage for using the circlize package directly is for plotting a circular dendrogram so that
you can add more graphics for the elements in the tree just by adding more tracks using circos.track.

Usage

circlize_dendrogram(dend, facing = c("outside", "inside"), labels = TRUE,
  labels_track_height = 0.1, dend_track_height = 0.5, ...)

Arguments

dend       a dendrogram object
facing     Is the dendromgrams facing inside to the circle or outside.
labels     logical (TRUE) - should the labels be plotted as well.
labels_track_height
  a value for adjusting the room for the labels. It is 0.2 by default, but if NULL or
  NA, it will adjust automatically based on the max width of the labels. However,
  if this is too long, the plot will give an error: Error in check.track.position(track.index,
  track.start, track.height) : not enough space for cells at track index '2'.
dend_track_height
  a value for adjusting the room for the dendrogram.
...
  Ignored.
**Value**
The dend that was used for plotting.

**Author(s)**
Zuguang Gu, Tal Galili

**Source**
This code is based on the work of Zuguang Gu. If you use the function, please cite both dendextend (see: citation("dendextend")), as well as the circlize package (see: citation("circlize")).

# In the following we get the dendrogram but can also get extra information on top of it
circos.initialize("foo", xlim = c(0, 40))
circos.track(ylim = c(0, 1), panel.fun = function(x, y) {
  circos.rect(1:40-0.8, rep(0, 40), 1:40-0.2, runif(40), col = rand_color(40), border = NA)
}, bg.border = NA)
circos.track(ylim = c(0, 1), panel.fun = function(x, y) {
  circos.text(1:40-0.5, rep(0, 40), labels(dend), col = labels_colors(dend),
  facing = "clockwise", niceFacing = TRUE, adj = c(0, 0.5))
}, bg.border = NA, track.height = 0.1)
max_height = attr(dend, "height")
circos.track(ylim = c(0, max_height), panel.fun = function(x, y) {
  circos.dendrogram(dend, max_height = max_height)
}, track.height = 0.5, bg.border = NA)
circos.clear()

## End(Not run)
**click_rotate**  
*Interactively rotate a tree object*

**Description**

Lets the user click a plot of dendrogram and rotates the tree based on the location of the click.

Code for mouse selection of (sub-)cluster to be rotated

**Usage**

```r
click_rotate(x, ...)  
## Default S3 method:
click_rotate(x, ...)  
## S3 method for class 'dendrogram'
click_rotate(x, plot = TRUE, plot_after = plot,  
horiz = FALSE, continue = FALSE, ...)
```

**Arguments**

- `x` a tree object (either a dendrogram or hclust)
- `...` parameters passed to the plot
- `plot` (logical) should the dendrogram first be plotted.
- `plot_after` (logical) should the dendrogram be plotted after the rotation?
- `horiz` logical. Should the plot be normal or horizontal?
- `continue` logical. If TRUE, allows the user to keep clicking the plot until a click is made on the labels.

**Value**

A rotated tree object

**Author(s)**

Andrej-Nikolai Spiess, Tal Galili

**See Also**

`rotate.dendrogram`
Examples

```r
# create the dend:

dend <- USArrests %>% dist %>% hclust("ave") %>%
as.dendrogram %>% color_labels

## Not run:
# play with the rotation once

dend <- click_rotate(dend)

dend <- click_rotate(dend, horiz = TRUE)

# keep playing with the rotation:
while(TRUE) dend <- click_rotate(dend)

# the same as

dend <- click_rotate(dend, continue = TRUE)

## End(Not run)
```

---

**collapse_branch**  
*Collapse branches under a tolerance level*

**Description**

Collapse branches under a tolerance level

**Usage**

```r
collapse_branch(dend, tol = 1e-08, lower = TRUE, ...)
```

**Arguments**

- **dend**: dendrogram object
- **tol**: a numeric value giving the tolerance to consider a branch length significantly greater than zero
- **lower**: logical (TRUE). collapse branches which are lower than tol?
- **...**: passed on (not used)

**Value**

A dendrogram with both of the root’s branches of the same height

**See Also**

- `multi2di`
Examples

# # ladderize is like sort(..., type = "node")
dend <- iris[1:5,-5] %>% dist %>% hclust %>% as.dendrogram
par(mfrow = c(1,3))
dend %>% ladderize %>% plot(horiz = TRUE); abline(v = .2, col = 2, lty = 2)
dend %>% collapse_branch(tol = 0.2) %>% ladderize %>% plot(horiz = TRUE)
dend %>% collapse_branch(tol = 0.2) %>% ladderize %>%
    hang.dendrogram(hang = 0) %>% ladderize %>% plot(horiz = TRUE)

par(mfrow = c(1,2))
dend %>% collapse_branch(tol = 0.2, lower = FALSE) %>%
    plot(horiz = TRUE, main = "dendrogram")
library(ape)
dend %>% as.phylo %>% di2multi(tol = 0.2) %>% plot(main = "phylo")

---

colored_bars  

Add colored bars to a dendrogram

Description

Add colored bars to a dendrogram, usually corresponding to either clusters or some outside categorization.

Usage

colored_bars(colors, dend, rowLabels = NULL, cex.rowLabels = 0.9,
add = TRUE, y_scale, y_shift, text_shift = 1,
sort_by_labels_order = TRUE, horiz = FALSE, ...)

Arguments

colors  
Coloring of objects on the dendrogram. Either a vector (one color per object)
or a matrix (can also be an array or a data frame) with each column giving
one group with color per object. Each column will be plotted as a horizontal
row of colors (when horiz = FALSE) under the dendrogram. As long as
the sort_by_labels_order parameter is TRUE (default), the colors vector/matrix
should be provided in the order of the original data order (and it will be re-
ordered automatically to the order of the dendrogram)
dend  
a dendrogram object. If missing, the colors are plotted without and re-ordering
(this assumes that the colors are already ordered based on the dend’s labels) This
is also important in order to get the correct height/location of the colored bars
(i.e.: adjusting the y_scale and y_shift)
rowLabels  
Labels for the colorings given in colors. The labels will be printed to the left of
the color rows in the plot. If the argument is given, it must be a vector of length
equal to the number of columns in colors. If not given, names(colors) will
be used if available. If not, sequential numbers starting from 1 will be used.
cex.rowLabels  
Font size scale factor for the row labels. See par.
colored_bars

add logical(TRUE), should the colored bars be added to an existing dendrogram plot?
y_scale how much should the bars be stretched on the y axis? If no dend is supplied - the default will be 1
y_shift where should the bars be plotted underneath the x axis? By default it will try to locate the bars underneath the labels (it may miss, in which case you would need to enter a number manually) If no dend is supplied - the default will be 0
text_shift a dendrogram object
sort_by_labels_order logical(TRUE) - if TRUE (default), then the order of the colored bars will be sorted based on the order needed to change the original order of the observations to the current order of the labels in the dendrogram. If FALSE the colored bars are plotted as-is, based on the order of the colors vector.
horiz logical (FALSE by default). Set to TRUE when using plot(dend, horiz = TRUE)
...

Details

You will often needs to adjust the y_scale, y_shift and the text_shift parameters, in order to get the bars in the location you would want.

(this can probably be done automatically, but will require more work. since it has to do with the current mar settings, the number of groups, and each computer’s specific graphic device. patches for smarter defaults will be appreciated)

Value

An invisible vector/matrix with the ordered colors.

Author(s)

Steve Horvath <SHorvath@mednet.ucla.edu>, Peter Langfelder <Peter.Langfelder@gmail.com>, Tal Galili <Tal.Galili@gmail.com>

Source

This function is based on the plotHclustColors from the moduleColor R package. It was modified so that it would work with dendrograms (and not just hclust objects), as well allow to add the colored bars on top of an existing plot (and not only as a separate plot).

See: https://cran.r-project.org/package=moduleColor For more details.

rows_picking <- c(1:5, 25:30)
dend <- as.dendrogram(iris[rows_picking,-5]*10)
odd_numbers <- rows_picking %% 2
cols <- c("gold", "grey")[odd_numbers+1]
# scale is off
plot(dend)
colored_bars(cols, dend)
# move and scale a bit
plot(dend)
colored_bars(cols, dend, y_shift = -1,
             rowLabels = "Odd\n numbers")
# Now let's cut the tree and add that info to the plot:
k2 <- cutree(dend, k = 2)
cols2 <- c("#0082CE", "#CC476B")[k2]
plot(dend)
colored_bars(cbind(cols2, cols), dend,
              rowLabels = c("2 clusters", "Odd numbers"))

# The same, but with an horizontal plot!
par(mar = c(6,2,2,4))
plot(dend, horiz = TRUE)
colored_bars(cbind(cols2, cols), dend,
              rowLabels = c("2 clusters", "Odd numbers"),
              horiz = TRUE)

# let's add clusters color
# notice how we need to play with the colors a bit
# this is because color_branches places colors from
# left to right. Which means we need to give colored_bars
# the colors of the items so that after sorting they would be
# from left to right. Here is how it can be done:
the_k <- 3
library(colorspace)
cols3 <- rainbow_hcl(the_k, c=90, l=50)
dend %>% set("branches_k_color", k = the_k, with = cols3) %>% plot

kx <- cutree(dend, k = the_k)
ord <- order.dendrogram(dend)
kx <- sort_levels_values(kx[ord])
kx <- kx[match(seq_along(ord), ord)]

par(mar = c(5,5,2,2))
plot(dend)
colored_bars(cbind(cols3[kx], cols2, cols), dend,
              rowLabels = c("3 clusters", "2 clusters", "Odd numbers"))
```
## colored_dots

**Add colored dots beside a dendrogram**

**Description**

Add colored dots next to a dendrogram, usually corresponding to either clusters or some outside categorization.
Usage

colored_dots(colors, dend, rowLabels = NULL, cex.rowLabels = 0.9,
  add = TRUE, y_scale, y_shift, text_shift = 1,
  sort_by_labels_order = TRUE, horiz = FALSE, ...)  

Arguments

colors  Coloring of the dots beside the dendrogram. Either a vector (one color per object) or a matrix (can also be an array or a data frame) with each column giving one group with color per object. Each column will be plotted as a colored point (when horiz = FALSE) under the dendrogram. As long as the sort_by_labels_order parameter is TRUE (default), the colors vector/matrix should be provided in the order of the original data order (and it will be re-ordered automatically to the order of the dendrogram)
dend  a dendrogram object. If missing, the colors are plotted without and re-ordering (this assumes that the colors are already ordered based on the dend's labels) This is also important in order to get the correct height/location of the colored dots (i.e.: adjusting the y_scale and y_shift)
rowLabels  Labels for the colorings given in colors. The labels will be printed to the left of the color rows in the plot. If the argument is given, it must be a vector of length equal to the number of columns in colors. If not given, names(colors) will be used if available. If not, sequential numbers starting from 1 will be used.
cex.rowLabels  Font size scale factor for the row labels. See par.
add  logical(TRUE), should the colored dots be added to an existing dendrogram plot?
y_scale  how much should the dots be stretched on the y axis? If no dend is supplied - the default will be 1
y_shift  where should the dots be plotted underneath the x axis? By default it will try to locate the dots underneath the labels (it may miss, in which case you would need to enter a number manually) If no dend is supplied - the default will be 0
text_shift  a dendrogram object
sort_by_labels_order  logical(TRUE) - if TRUE (default), then the order of the colored dots will be sorted based on the order needed to change the original order of the observations to the current order of the labels in the dendrogram. If FALSE the colored dots are plotted as-is, based on the order of the colors vector.
horiz  logical (FALSE by default). Set to TRUE when using plot(dend, horiz = TRUE)
...  ignored at this point.

Details

The reason you might choose colored_dots over colored_bars is when you have a lot of group types and/or a really large dendrogram. Hint: Make a group for each categorical factor and color it one color when true, and assign a fully transparent color when false.

You will often need to adjust the y_scale, y_shift and the text_shift parameters, in order to get the dots in the location you would want.
(This can probably be done automatically, but will require more work, since it has to do with the current mar settings, the number of groups, and each computer’s specific graphic device. Patches for smarter defaults will be appreciated)

**Value**

An invisible vector/matrix with the ordered colors.

**Author(s)**

Steve Horvath <shorvath@mednet.ucla.edu>, Tal Galili <Tal.Galili@gmail.com>, Peter Langfelder <Peter.Langfelder@gmail.com>, Chase Clark <chasec288@gmail.com>

**Source**

This function is based on the `plotHclustColors` from the `moduleColor` R package. It was modified so that it would work with dendrograms (and not just hclust objects), as well allow to add the colored dots on top of an existing plot (and not only as a separate plot).

See: [https://cran.r-project.org/package=moduleColor](https://cran.r-project.org/package=moduleColor) For more details.

**Examples**

```r
rows_picking <- c(1:5, 25:30)
dend <- (iris[rows_picking,-5]*10) %>% dist %>% hclust %>% as.dendrogram
odd_numbers <- rows_picking %% 2
cols <- c("red", "white")[odd_numbers+1]
plot(dend)
colored_dots(cols, dend)
# Example of adjusting position of dots
plot(dend)
colored_dots(cols, dend, y_shift = -1,
            rowLabels = "Odd\n numbers")
rows_picking <- c(1:5, 25:30)
dend <- (iris[rows_picking,-5]*10) %>% dist %>% hclust %>% as.dendrogram
odd_numbers <- rows_picking %% 2
# For leaves that shouldn't have dots, make them the same color as the background,
# or set the alpha value to fully transparant
cols <- c("black", "white")[odd_numbers+1]
# scale is off
plot(dend)
colored_dots(cols, dend)
# move and scale a bit
plot(dend)
colored_dots(cols, dend, y_shift = -1,
            rowLabels = "Odd\n numbers")
# Now let's cut the tree and add that info to the plot:
```
```r

k2 <- cutree(dend, k = 2)
cols2 <- c("#1b9e77", "#d95f02")[k2]

par(mar = c(5,6,1,1))
plot(dend)
colored_dots(cbind(cols2, cols), dend,
  rowLabels = c("2 clusters", "Even numbers"))

# The same, but with an horizontal plot!
par(mar = c(6,2,2,4))
plot(dend, horiz = TRUE)
colored_dots(cbind(cols2, cols), dend,
  rowLabels = c("2 clusters", "Even numbers"),
  horiz = TRUE)

# Mtcars example

# Create the dend:
dend <- as.dendrogram(hclust(dist(mtcars)))

# Get all company names
comp_names <- unlist(lapply(rownames(mtcars), function(x) strsplit(x, "\([\)]\)[1][1][1]))
# Get the top three occurring companies
top_three <- sort(table(comp_names), decreasing = TRUE)[1:3]
# Match the top three companies to where they are found in the dendrogram labels
top_three <- sapply(names(top_three), function(x) grepl(x, labels(dend)))

# "top_three" is now a data frame of the top three companies as columns.
# Each column represents a vector (rows) which is the length of labels(dend).
# The vector has values TRUE and FALSE, for whether the company name matched
# labels(dend)[i]

colorblind_friendly <- c("#1b9e77", "#d95f02", "#7570b3")

# If we run the for-loop on "top_three" we will turn the vectors into a character-type too early,
# so make a copy to "colored_dataframe" which we will work on
colored_dataframe <- top_three

for (i in 1:3){
  # This replaces TRUE values with a color from our vector of colors
  colored_dataframe[top_three[,i]] <- colorblind_friendly[i]
  # This replaces FALSE values with black HEX, but fully transparent (invisible on plot)
  colored_dataframe[!top_three[,i]] <- "#00000000"
}

# Color branches and labels by "cutting" the dendrogram at an arbitrary height
dend <- color_branches(dend, h = 170)
dend <- color_labels(dend, h = 170)
```
# color_branches

Color tree's branches according to sub-clusters

**Description**

This function is for dendrogram and hclust objects. This function colors both the terminal leaves of a dend's cluster and the edges leading to those leaves. The edgePar attribute of nodes will be augmented by a new list item col. The groups will be defined by a call to `cutree` using the k or h parameters.

If col is a color vector with a different length than the number of clusters (k) - then a recycled color vector will be used.

**Usage**

```r
color_branches(dend, k = NULL, h = NULL, col, groupLabels = NULL, clusters, warn = dendextend_options("warn"), ...)
```

**Arguments**

- **dend**: A dendrogram or hclust tree object
- **k**: number of groups (passed to `cutree`)
- **h**: height at which to cut tree (passed to `cutree`)
- **col**: Function or vector of Colors. By default it tries to use `rainbow_hcl` from the `colorspace` package. (with parameters c=90 and l=50). If `colorspace` is not available, It will fall back on the `rainbow` function.
- **groupLabels**: If TRUE add numeric group label - see Details for options
- **clusters**: an integer vector of clusters. This is passed to `branches_attr_by_clusters`. This HAS to be of the same length as the number of leaves. Items that belong to no cluster should get the value 0. The vector should be of the same order as that of the labels in the dendrogram. If you create the clusters from something like `cutree` you would first need to use `order.dendrogram` on it, before using it in the function.
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

... ignored.

Details

If groupLabels=TRUE then numeric group labels will be added to each cluster. If a vector is supplied then these entries will be used as the group labels. If a function is supplied then it will be passed a numeric vector of groups (e.g. 1:5) and must return the formatted group labels.

If the labels of the dendrogram are NOT character (but, for example integers) - they are coerced into character. This step is essential for the proper operation of the function. A dendrogram labels might happen to be integers if they are based on an hclust performed on a dist of an object without rownames.

Value

a tree object of class dendrogram.

Author(s)

Tal Galili, extensively based on code by Gregory Jefferis

Source

This function is a derived work from the color_clusters function, with some ideas from the slice function - both are from the dendroextras package by jefferis.

It extends it by using cutree.dendrogram - allowing the function to work for trees that hclust can not handle (unbranched and non-ultrametric trees). Also, it allows REPEATED cluster color assignments to branches on to the same tree. Something which the original function was not able to handle.

## End(Not run)

color_labels

**Color dend's labels according to sub-clusters**

**Description**

This function is for dendrogram and hclust objects. This function colors tree's labels.

The groups will be defined by a call to 
`cutree` using the k or h parameters.

If col is a color vector with a different length than the number of clusters (k) - then a recycled color vector will be used.

**Usage**

```r
color_labels(dend, k = NULL, h = NULL, labels, col,
            warn = dendextend_options("warn"), ...)```

**Arguments**

- **dend**: A dendrogram or hclust tree object
- **k**: number of groups (passed to `cutree`)
- **h**: height at which to cut tree (passed to `cutree`)
- **labels**: character vector. If not missing, it overrides k and h, and simply colors these labels in the tree based on "col" parameter.
- **col**: Function or vector of Colors. By default it tries to use `rainbow_hcl` from the `colorspace` package. (with parameters c=90 and l=50). If `colorspace` is not available, It will fall back on the `rainbow` function.
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. (in case h/k/labels are not supplied, or if col is too short) ignored.

Value

a tree object of class dendrogram.

Source

This function is in the style of color_branches, and based on labels_colors.

cutree, dendrogram, hclust, labels_colors, color_branches, assign_values_to_leaves_edgePar

Examples

```r
## Not run:
hc <- hclust(dist(USArrests), "ave")
dend <- as.dendrogram(hc)
dend=color_labels(dend,5, col = c(3,1,1,4,1))
dend=color_branches(dend,5, col = c(3,1,1,4,1))
plot(dend) # selective coloring of branches AND labels :

# coloring some labels, based on label names:
dend=color_labels(dend, col = "red", labels = labels(dend)[c(4,16)])
plot(dend) # selective coloring of branches AND labels :

d5=color_branches(dend,5)
plot(d5)
d5g=color_branches(dend,5,groupLabels=TRUE)
plot(d5g)
d5gr=color_branches(dend,5,groupLabels=as.roman)
plot(d5gr)

## End(Not run)
```

---

color_unique_labels  Color unique labels in a dendrogram

Description

Color unique labels in a dendrogram
Usage

color_unique_labels(dend, ...)

Arguments

dend a dend object

... NOT USED

Value

A dendrogram after the colors of its labels have been updated (a different color for each unique label).

Examples

```r
names(x) <- x
dend <- as.dendrogram(hclust(dist(x)))

par(mfrow = c(1,2))
plot(dend)
dend2 <- color_unique_labels(dend)
plot(dend2)
```

---

common_subtrees_clusters

*Find clusters of common subtrees*

Description

Gets a dend and the output from "nodes_with_shared_labels" and returns a vector (length of labels), indicating the clusters forming shared subtrees.

Usage

```r
common_subtrees_clusters(dend1, dend2, leaves_get_0_cluster = TRUE, ...)
```

Arguments

dend1 a dendrogram.
dend2 a dendrogram.
leaves_get_0_cluster

logical (TRUE). Should the leaves which are not part of a larger common subtree get a unique cluster number, or the value 0.

... not used.
Value

An integer vector, with values indicating which leaves in dend1 form a common subtree cluster, with ones available in dend2

See Also

color_branches, tanglegram

Examples

library(dendextend)
dend1 <- 1:6 %>% dist %>% hclust %>% as.dendrogram
dend2 <- dend1 %>% set("labels", c(1:4,6:5))

clusters1 <- common_subtrees_clusters(dend1, dend2)
dend1_2 <- color_branches(dend1, clusters = clusters1)
plot(dend1_2)
plot(dend1_2, horiz = TRUE)
tanglegram(dend1_2, dend2, highlight_distinct_edges = FALSE)
tanglegram(dend1_2, dend2)

---

cor.dendlist Correlation matrix between a list of trees.

Description

A correlation matrix between a list of trees.
Assumes the labels in the two trees fully match. If they do not please first use intersect_trees to have them matched.

Usage

cor.dendlist(dend, method = c("cophenet", "baker", "common_nodes", "FM_index"), ...)

Arguments

dend a dendlist of trees
method a character string indicating which correlation coefficient is to be computed. One of "cophenet" (default), "baker", "common_nodes", or "FM_index". It can be abbreviated.
... passed to cor functions.
cor_bakers_gamma

Value

A correlation matrix between the different trees

See Also

cophenetic, cor_cophenetic, cor_bakers_gamma, cor_common_nodes, cor_FM_index

Examples

```r
## Not run:

set.seed(23235)
ss <- sample(1:150, 10)
dend1 <- iris[ss,-5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[ss,-5] %>% dist %>% hclust("single") %>% as.dendrogram
dend3 <- iris[ss,-5] %>% dist %>% hclust("ave") %>% as.dendrogram
dend4 <- iris[ss,-5] %>% dist %>% hclust("centroid") %>% as.dendrogram
# cutree(dend1)
cors <- cor.dendlist(dendlist(d1 = dend1, d2 = dend2, d3 = dend3, d4 = dend4))

cors

# a nice plot for them:
library(corrplot)
corrplot(corr(dendlist(d1234), "pie", "lower")

## End(Not run)
```

---

cor_bakers_gamma  
Baker’s Gamma correlation coefficient

Description

Calculate Baker’s Gamma correlation coefficient for two trees (also known as Goodman-Kruskal-gamma index).

Assumes the labels in the two trees fully match. If they do not please first use intersect_trees to have them matched.

WARNING: this can be quite slow for medium/large trees.

Usage

```r
cor_bakers_gamma(dend1, ...)
```

## Default S3 method:
```r
cor_bakers_gamma(dend1, dend2, ...)
```
## Arguments

- **dend1**: a tree (dendrogram/hclust/phylo)
  - Passed to `cutree`.
- **dend2**: a tree (dendrogram/hclust/phylo)
- **use_labels_not_values**: logical (TRUE). Should labels be used in the k matrix when using `cutree`? Set to FALSE will make the function a bit faster BUT, it assumes the two trees have the exact same leaves order values for each labels. This can be assured by using `match_order_by_labels`.
- **to_plot**: logical (FALSE). Passed to `bakers_gamma_for_2_k_matrix`
- **warn**: logical (default from `dendextend_options("warn")` is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. should a warning be issued when using `cutree`?
- **which**: an integer vector of length 2, indicating which of the trees in the dendlist object should be plotted (relevant for dendlist)

## Details

Baker's Gamma (see reference) is a measure of association (similarity) between two trees of hierarchical clustering (dendrograms).

It is calculated by taking two items, and see what is the highest possible level of k (number of cluster groups created when cutting the tree) for which the two item still belongs to the same tree. That k is returned, and the same is done for these two items for the second tree. There are n over 2 combinations of such pairs of items from the items in the tree, and all of these numbers are calculated for each of the two trees. Then, these two sets of numbers (a set for the items in each tree) are paired according to the pairs of items compared, and a spearman correlation is calculated.

The value can range between -1 to 1. With near 0 values meaning that the two trees are not statistically similar. For exact p-value one should result to a permutation test. One such option will be to permute over the labels of one tree many times, and calculating the distribution under the null hypothesis (keeping the trees topologies constant).

Notice that this measure is not affected by the height of a branch but only of its relative position compared with other branches.
cor_bakers_gamma

Value

Baker’s Gamma association Index between two trees (a number between -1 to 1)

References

cor_cophenetic

Examples

## Not run:

```r
set.seed(23235)
ss <- sample(1:150, 10)
hcl1 <- hclust(dist(iris[ss,-5]), "com")
hc2 <- hclust(dist(iris[ss,-5]), "single")
dend1 <- as.dendrogram(hcl1)
dend2 <- as.dendrogram(hc2)
# cutree(dend1)
cor_bakers_gamma(hcl1, hc2)
cor_bakers_gamma(dend1, dend2)

dend1 <- match_order_by_labels(dend1, dend2) # if you are not sure
cor_bakers_gamma(dend1, dend2, use_labels_not_values = FALSE)

library(microbenchmark)
microbenchmark(
  with_labels = cor_bakers_gamma(dend1, dend2, try_cutree_hclust=FALSE) ,
  with_values = cor_bakers_gamma(dend1, dend2,
  use_labels_not_values = FALSE, try_cutree_hclust=FALSE) ,
  times=10
)

cor_bakers_gamma(dend1, dend1, use_labels_not_values = FALSE)
cor_bakers_gamma(dend1, dend1, use_labels_not_values = TRUE)

## End(Not run)
Proportion of common nodes between two trees

Description

Calculates the number of nodes, in each tree, that are common (i.e.: that have the same exact list of labels). The correlation is between 0 (actually, $2*(\text{nnodes}-1)/(2*\text{nnodes})$, for two trees with the same list of labels - since the top node will always be identical for them). Where 1 means that every node in the one tree, has a node in the other tree with the exact same list of labels. Notice this measure is non-parameteric (it ignores the heights and relative position of the nodes).

Usage

```r
cor_common_nodes(dend1, dend2, ...)
```

Arguments

- `dend1`: a dendrogram.
- `dend2`: a dendrogram.
- `...`: not used.

Value

A correlation value between 0 to 1 (almost identical trees)

See Also

- `distinct_edges`, `cor.dendlist`

Examples

```r
set.seed(23235)
s <- sample(1:150, 10 )
hc1 <- iris[s, -5] %>% dist %>% hclust("com")
hc2 <- iris[s, -5] %>% dist %>% hclust("single")
dend1 <- as.dendrogram(hc1)
dend2 <- as.dendrogram(hc2)
cor_cophenetic(dend1, dend2)
cor_common_nodes(dend1, dend2)
tanglegram(dend1, dend2)
# we can see we have only two nodes which are different...
```
**Cor_cophenetic**

**Cophenetic correlation between two trees**

**Description**

Cophenetic correlation coefficient for two trees. Assumes the labels in the two trees fully match. If they do not please first use `intersect_trees` to have them matched.

**Usage**

```r
cor_cophenetic(dend1, ...)  
```

## Default S3 method:
```r  
cor_cophenetic(dend1, dend2, method_coef = c("pearson",  
  "kendall", "spearman"), ...)  
```

## S3 method for class 'dendlist'
```r  
cor_cophenetic(dend1, which = c(1L, 2L),  
  method_coef = c("pearson", "kendall", "spearman"), ...)  
```

**Arguments**

- `dend1` a tree (dendrogram/hclust/phylo, or dendlist)
- `...` Ignored.
- `dend2` Either a tree (dendrogram/hclust/phylo), or a `dist` object (for example, from the original data matrix).
- `method_coef` a character string indicating which correlation coefficient is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated. Passed to `cor`.
- `which` an integer vector of length 2, indicating which of the trees in a dendlist object should have their `cor_cophenetic` calculated.

**Details**

From `cophenetic`: The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

`cor_cophenetic` calculates the correlation between two cophenetic distance matrices of the two trees. The value can range between -1 to 1. With near 0 values meaning that the two trees are not statistically similar. For exact p-value one should result to a permutation test. One such option will be to permute over the labels of one tree many times, and calculating the distribution under the null hypothesis (keeping the trees topologies constant).

Notice that this measure IS affected by the height of a branch.
cor_cophenetic

Value

The correlation between cophenetic

References

http://en.wikipedia.org/wiki/Cophenet correlation

See Also

cophenetic, cor_bakers_gamma

Examples

```r
## Not run:

set.seed(23235)
ss <- sample(1:150, 10)
hc1 <- iris[ss,-5] %>% dist %>% hclust("com")
hc2 <- iris[ss,-5] %>% dist %>% hclust("single")
dend1 <- as.dendrogram(hc1)
dend2 <- as.dendrogram(hc2)
  #   cutree(dend1)

cophenetic(hc1)
cophenetic(hc2)
  # notice how the dist matrix for the dendrograms have different orders:
cophenetic(dend1)
cophenetic(dend2)

cor(cophenetic(hc1), cophenetic(hc2)) # 0.874

cor(cophenetic(dend1), cophenetic(dend2)) # 0.16

  # the difference is because the order of the distance table in the case of
  # stats::cophenetic.dendrogram will change between dendrograms!

  # however, this is consistent (since I force-sort the rows/columns):
cor.cophenetic(hc1, hc2)
cor.cophenetic(dend1, dend2)

  cor.cophenetic(dendlist(dend1, dend2))

  # we can also use different cor methods (almost the same result though):
cor.cophenetic(hc1, hc2, method = "spearman") # 0.8456014

cor.cophenetic(dend1, dend2, method = "spearman") #

  # cophenetic correlation is about 10 times (!) faster than bakers.gamma cor:
```
**cor_FM_index**

Correlation of FM_index for some k

Description

Calculates the FM_index Correlation for some k.

Usage

```r
cor_FM_index(dend1, dend2, k, ...) 
```

Arguments

- `dend1` : a dendrogram.
- `dend2` : a dendrogram.
- `k` : an integer (number of clusters to cut the tree)
- `...` : not used.

Value

A correlation value between 0 to 1 (almost identical clusters for some k)

See Also

FM_index, cor.dendlist, Bk
count_terminal_nodes

Counts the number of terminal nodes (merging 0 nodes!)

Description

This function counts the number of "practical" terminal nodes (nodes which are not leaves, but has
0 height to them are considered "terminal" nodes). If the tree is standard, that would simply be the
number of leaves (only the leaves will have height 0). However, in cases where the tree has several
nodes (before the leaves) with 0 height, the count_terminal_nodes counts such nodes as terminal
nodes.

The function is recursive in that it either returns 1 if it reached a terminal node (either a leaf or a 0
height node), else: it will count the number of terminal nodes in each of its sub-nodes, sum them
up, and return them.

Usage

count_terminal_nodes(dend_node, ...)

Arguments

dend_node a dendrogram object for which to count its number of terminal nodes (leaves or
0 height nodes).

... not used

Value

The number of terminal nodes (excluding the leaves of nodes of height 0)
Examples

# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:3,]), "ave")
dend <- as.dendrogram(hc)

###
# Trivial case
count_terminal_nodes(dend) # 3 terminal nodes
length(labels(dend)) # 3 - the same number
plot(dend,
main = "This is considered a tree \n with THREE terminal nodes (leaves)"
)

###
# NON-Trivial case
str(dend)
attr(dend[[2]], "height") <- 0
count_terminal_nodes(dend) # 2 terminal nodes, why? see this plot:
plot(dend,
main = "This is considered a tree \n with TWO terminal nodes only")
# while we have 3 leaves, in practice we have only 2 terminal nodes
# (this is a feature, not a bug.)

---

cutree

Cut a Tree (Dendrogram/hclust/phylo) into Groups of Data

Description

Cuts a dendrogram tree into several groups by specifying the desired number of clusters k(s), or cut height(s).

For hclust.dendrogram - In case there exists no such k for which exists a relevant split of the dendrogram, a warning is issued to the user, and NA is returned.

Usage

cutree(tree, k = NULL, h = NULL, ...)

## Default S3 method:
cutree(tree, k = NULL, h = NULL, ...)

## S3 method for class 'hclust'
cutree(tree, k = NULL, h = NULL,
use_labels_not_values = TRUE, order_clusters_as_data = TRUE,
warn = dendextend_options("warn"), NA_to_0L = TRUE, ...)

## S3 method for class 'phylo'
cutree(tree, k = NULL, h = NULL, ...)

## S3 method for class 'phylo'
cutree(tree, k = NULL, h = NULL, ...)

## S3 method for class 'agnes'
cutree(tree, k = NULL, h = NULL, ...)

## S3 method for class 'diana'
cutree(tree, k = NULL, h = NULL, ...)

## S3 method for class 'dendrogram'
cutree(tree, k = NULL, h = NULL,
        dend_heights_per_k = NULL, use_labels_not_values = TRUE,
        order_clusters_as_data = TRUE, warn = dendextend_options("warn"),
        try_cutree_hclust = TRUE, NA_to_0L = TRUE, ...)

Arguments

tree a dendrogram object

k numeric scalar (OR a vector) with the number of clusters the tree should be cut into.

h numeric scalar (OR a vector) with a height where the tree should be cut.

... (not currently in use)

use_labels_not_values logical, defaults to TRUE. If the actual labels of the clusters do not matter - and we want to gain speed (say, 10 times faster) - then use FALSE (gives the "leaves order" instead of their labels.). This is passed to cutree_hcl.dendrogram.

order_clusters_as_data logical, defaults to TRUE. There are two ways by which to order the clusters: 1) By the order of the original data. 2) by the order of the labels in the dendrogram. In order to be consistent with cutree, this is set to TRUE. This is passed to cutree_hcl.dendrogram.

warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. Should the function send a warning in case the desired k is not available?

NA_to_0L logical. default is TRUE. When no clusters are possible. Should the function return 0 (TRUE, default), or NA (when set to FALSE).

dend_heights_per_k a named vector that resulted from running heights_per_k.dendrogram. When running the function many times, supplying this object will help improve the running time if using k!=NULL.

try_cutree_hclust logical. default is TRUE. Since cutree for hclust is MUCH faster than for dendrogram - cutree.dendrogram will first try to change the dendrogram into an hclust object. If it will fail (for example, with unbranched trees), it will continue using the cutree.dendrogram function. If try_cutree_hclust=FALSE, it will force to use cutree.dendrogram and not cutree.hclust.
Details

At least one of k or h must be specified, k overrides h if both are given.

as opposed to `cutree` for hclust, `cutree` allows the cutting of trees at a given height also for non-ultrametric trees (ultrametric tree == a tree with monotone clustering heights).

Value

If k or h are scalar - `cutree` returns an integer vector with group memberships. Otherwise a matrix with group memberships is returned where each column corresponds to the elements of k or h, respectively (which are also used as column names).

In case there exists no such k for which exists a relevant split of the dendrogram, a warning is issued to the user, and NA is returned.

Author(s)

cutree was written by Tal Galili. `cutree` is redirecting the function to `cutree` from base R.

## There were 50 or more warnings (use warnings() to see the first 50)

# notice that if cutree can't find clusters for the desired k/h, it will produce 0's instead!
# (It will produce a warning though...)  
# This is a different behaviour than stats::cutree  
# For example:
# cutree(as.dendrogram(hclust(dist(c(1,1,1,1,2,2)))),
# k=5)

## End(Not run)
Description

Cuts a dendrogram tree into several groups by specifying the desired cut height (only a single height!).

Usage

cutree_1h.dendrogram(dend, h, order_clusters_as_data = TRUE, 
use_labels_not_values = TRUE, warn = dendextend_options("warn"), ...)

Arguments

dend: a dendrogram object
h: numeric scalar (NOT a vector) with a height where the dend should be cut.
order_clusters_as_data: logical, defaults to TRUE. There are two ways by which to order the clusters: 1) By the order of the original data. 2) by the order of the labels in the dendrogram. In order to be consistent with cutree, this is set to TRUE.
use_labels_not_values: logical, defaults to TRUE. If the actual labels of the clusters do not matter - and we want to gain speed (say, 10 times faster) - then use FALSE (gives the "leaves order" instead of their labels.).
warn: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
...
(not currently in use)

Value

cutree_1h.dendrogram returns an integer vector with group memberships

---

**cutree_1k.dendrogram**  
*cutree for dendrogram (by 1 k value only!)*

---

**Description**

Cuts a dendrogram tree into several groups by specifying the desired number of clusters k (only a single k value!).

In case there exists no such k for which exists a relevant split of the dendrogram, a warning is issued to the user, and NA is returned.

**Usage**

```
cutree_1k.dendrogram(dend, k, dend_heights_per_k = NULL,
                      use_labels_not_values = TRUE, order_clusters_as_data = TRUE,
                      warn = dendextend_options("warn"), ...)
```

**Arguments**

- `dend`  
a dendrogram object
- `k`  
numeric scalar (not a vector!) with the number of clusters the tree should be cut into.
- `dend_heights_per_k`  
a named vector that resulted from running `heights_per_k.dendrogram`. When running the function many times, supplying this object will help improve the running time.
- `use_labels_not_values`  
logical, defaults to TRUE. If the actual labels of the clusters do not matter - and we want to gain speed (say, 10 times faster) - then use FALSE (gives the "leaves order" instead of their labels.). This is passed to `cutree_1h.dendrogram`.  

**cutree_1k.dendrogram**

**order_clusters_as_data**

logical, defaults to TRUE. There are two ways by which to order the clusters: 1) By the order of the original data. 2) by the order of the labels in the dendrogram. In order to be consistent with `cutree`, this is set to TRUE. This is passed to `cutree_1h.dendrogram`.

**warn**

logical (default from `dendextend_options("warn")` is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. Should the function send a warning in case the desired `k` is not available?

... (not currently in use)

**Value**

`cutree_1k.dendrogram` returns an integer vector with group memberships.

## End(Not run)

---

cut_lower_fun  
*Cut a dendrogram - and run a function on the output*

### Description

Cuts the dend at height h and returns a list with the FUN function implemented on all the sub trees created by cut at height h. This is used for creating a `cutree.dendrogram` function, by using the `labels` function as FUN.

This is the Rcpp version of the function, offering a 10-60 times improvement in speed (depending on the tree size it is used on).

### Usage

```r
cut_lower_fun(dend, h, FUN = labels, warn = dendextend_options("warn"), ...)
```

### Arguments

- **dend**: a dendrogram object.
- **h**: a scalar of height to cut the dend by.
- **FUN**: a function to run. (default is "labels")
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. Should the user be warned if reverting to default?
- **...**: passed to FUN.

### Value

A list with the output of running FUN on each of the sub dendrs derived from cutting "dend"

### Author(s)

Tal Galili

### See Also

- `labels`, `dendrogram`, `cutree.dendrogram`
Examples

d = as.dendrogram(hclust(dist(iris[1:4,-5])))
# this is really cool!
cut_lower_fun(d, .4, labels)
lapply(cut(d, h = .4)$lower, labels)
cut_lower_fun(dend, .4, order.dendrogram)

## Not run:
# library(dendextend)
library(dendextendRcpp)
dend_big = as.dendrogram(hclust(dist(iris[1:150,-5])))
library(microbenchmark)
microbenchmark(old_cut_lower_fun(dend_big, .1),
     dendextendRcpp::dendextendRcpp_cut_lower_fun(dend_big, .1),
     times = 100)
# about 7-15 times faster. It is faster the larger the tree is, and the lower h is.
## End(Not run)

d3dendrogram

Plot dendrogram to webpage and view.

Description

Plot dendrogram to webpage and view.

Usage

d3dendrogram(d, height = 500, width = 700, rightmargin = 200,
open = TRUE, ...)

Arguments

d a dendrogram object
height pixels, height of the plot.
width pixels, width of the plot
rightmargin pixels to reserve on the right side for leaf labels.
open open the graphic in a browser? (see details).
... Graphical options, see d3dendro_options.

Details

If open=TRUE, the graphic is opened using the function defined by getOption("viewer"). If no viewer option is specified, utils::browseURL is opened. Specifically, in RStudio this means that the viewer is used.
Value

If open=TRUE, a character string containing the html is invisibly returned. If open=TRUE, a character string containing the html is returned.

Tips

Dendrogram plots with many end-nodes tend to get overlapping labels or (end)nodes. If the number of endnodes is not too large, there are several ways to overcome this.

• Decrease font size of the nodes (node_font, see d3dendro_options on how to specify)
• Decrease size of node radius (node_radius, idem)
• Increase the height of the plot. Use about (2 times font height) times count_terminal_nodes(d).
• Plot sub-dendrograms in stead of the whole dendrogram. There’s only so much detail a screen can display and your eye can observe. Consider plotting subdendrograms or other summaries when dendrograms have many, many nodes.

d3dendro_options

Get or set current defaults for d3dendrogram

Description

Get or set current defaults for d3dendrogram

Usage

d3dendro_options(..., copy = FALSE)

Arguments

... <option>=<value> pairs (see below). If no option/value pair is given, a list with current settings is returned. If the single input "reset" is given, options are restored to factory settings.

copy only when options are set: set global options or return a modified copy of the global option environment invisibly?

Options

Option values are exported as-is to the generated javascript/webpage.

node_fill (char,"#fff") Node color (fill)
node_stroke (char;"steelblue") Node color (circumference)
node_stroke_width (char;"1.5px") Width of node circumference
node_radius (num;4.5) Size of node (pixels)
node_font (char;"14px sans-serif") Font used to print labels. Size and type spec
link_fill (char;"none") link fill color (you probably do not want to set this)
link_stroke (char;"#ccc") link line color (that’s the one you want)
dendextend_options

link_stroke_width (char;"1.5px") link line width (pixels)
axis_stroke (char;"black") Color of axis line
axis_width (char; "2px") Width of axis line
axis_ntick (num; 5) Approximate nr of tick marks
axis_ticklength_in (num;5) Length of tickmarks into the graph (pixels)
axis_ticklength_out (num;5) Length of tickmarks out of the graph (pixels)
axis_tickmark_offset (num;8) Distance between axis and tick labels (pixels)

---

**Description**

This is a function inside its own environment. This enables a bunch of functions to be manipulated outside the package, even when they are called from function within the dendextend package.

TODO: describe options.

A new "warn" dendextend_options parameter. logical (FALSE). Should warning be issued?

**Usage**

dendextend_options(option, value)

**Arguments**

- **option** a character scalar of the value of the options we would like to access or update.
- **value** any value that we would like to update into the "option" element in dendextend_options

**Value**

a list with functions

**Author(s)**

Kurt Hornik

**Examples**

dendextend_options("a")
dendextend_options("a", 1)
dendextend_options("a")
dendextend_options("a", NULL)
dendextend_options("a")
dendextend_options()
Creating a dendlist object from several dendrograms

Description

It accepts several dendrograms and or dendlist objects and chain them all together. This function aim to help with the usability of comparing two or more dendrograms.

Usage

dendlist(..., which)

## S3 method for class 'dendlist'
plot(x, which = c(1L, 2L), ...)

Arguments

... several dendrogram/hclust/phylo or dendlist objects If an object is hclust or phylo - it will be converted into a dendrogram.
which an integer vector of length 2, indicating which of the trees in the dendlist object should be plotted (relevant for dendlist)
   When used inside dendlist, which is still an integer, but it can be of any length, and it can be used to create a smaller dendlist.
   x a dendlist object

Details

   It there are list() in the ..., they are omitted. If ... is missing, it returns an empty dendlist.

Value

   A list of class dendlist where each item is a dendrogram

Examples

   # Not run:

dend <- iris[, -5] %>% dist %>% hclust %>% as.dendrogram
dend2 <- iris[, -5] %>% dist %>% hclust(method = "single") %>% as.dendrogram
dendlist(1:4, 5, a=dend) # Error
   # dendlist <- function (...) list(...) dendlist(dend)
dendlist(dend, dend)
dendlist(dend, dendlist(dend))
   # notice how the order of
dendlist(dend, dend2)
dendlist(dend) %>% dendlist(dend2)
DendSer.dendrogram

Tries to run DendSer on a dendrogram

Description

Implements dendrogram seriation. The function tries to turn the dend into hclust, on which it runs DendSer.

Also, if a distance matrix is missing, it will try to use the cophenetic distance.

Usage

DendSer.dendrogram(dend, ser_weight, ...)

Arguments

dend

An object of class dendrogram

ser_weight

Used by cost function to evaluate ordering. For cost=costLS, this is a vector of object weights. Otherwise is a dist or symmetric matrix. passed to DendSer. If it is missing, the cophenetic distance is used instead.

...

parameters passed to DendSer

Value

Numeric vector giving an optimal dendrogram order

See Also

DendSer, DendSer.dendrogram, untangle_DendSer, rotate_DendSer
dend_diff

Plots two trees side by side, highlighting edges unique to each tree in red.

Description

Plots two trees side by side, highlighting edges unique to each tree in red.

Usage

dend_diff(dend, ...)

## S3 method for class 'dendrogram'
dend_diff(dend, dend2, horiz = TRUE, ...)

## S3 method for class 'dendlist'
dend_diff(dend, ..., which = c(1L, 2L))

Arguments

dend

a dendrogram or dendlist to compare with

... passed to plot.dendrogram

dend2

a dendrogram to compare with

horiz

logical (TRUE) indicating if the dendrogram should be drawn horizontally or not.

which

an integer vector indicating, in the case "dend" is a dendlist, on which of the trees should the modification be performed. If missing - the change will be performed on all of objects in the dendlist.

Value

Invisible dendlist of both trees.

dend_expend

Description

There are many options for choosing distance and linkage functions for hclust. This function goes through various combinations of the two and helps find the one that is most "similar" to the original distance matrix.

Usage

dend_expend(x, dist_methods = c("euclidean", "maximum", "manhattan", "canberra", "binary", "minkowski"), hclust_methods = c("ward.D", "ward.D2", "single", "complete", "average", "mcquitty", "median", "centroid"), hclust_fun = hclust, optim_fun = cor_cophenetic, ...)

find_dend(x, ...)

Arguments

x A matrix or a data.frame. Can also be a dist object.
dist_methods A vector of possible dist methods.
hclust_methods A vector of possible hclust methods.
hclust_fun By default hclust.
optim_fun A function that accepts a dend and a dist and returns how the two are in agreement. Default is cor_cophenetic.
... options passed from find_dend to dend_expend.
Value

dend_expand: A list with three items. The first item is called "dends" and includes a dendlist with all the possible dendrogram combinations. The second is "dists" and includes a list with all the possible distance matrix combination. The third. "performance", is data.frame with three columns: dist_methods, hclust_methods, and optim. optim is calculated (by default) as the cophenetic correlation (see: cor_cophenetic) between the distance matrix and the cophenetic distance of the hclust object.

find_dend: A dendrogram which is "optimal" based on the output from dend_expand.

Examples

```r
x <- datasets::mtcars
out <- dend_expand(x, dist_methods = c("euclidean", "manhattan"))
out$performance

find_dend(out)

best_dend <- find_dend(x, dist_methods = c("euclidean", "manhattan"))
plot(best_dend)
```

---

dist.dendlist  Topological Distances Between Two Dendrograms

Description

This function computes the Robinson-Foulds distance (also known as symmetric difference) between two dendrograms. This is the sum of edges in both trees with labels that exist in only one of the two trees (i.e.: the length of distinct_edges).

This function might implement other topological distances in the future.

Usage

dist.dendlist(dend, method = c("edgeset"), ...)

Arguments

dend  a dendlist
method  currently only 'edgeset' is implemented.
...  Ignored.

Value

A dist object with topological distances between all trees
distinct_edges

See Also
distinct_edges, dist.topo, dist.multiPhylo, treeDist,

Examples

```r
x <- 1:5 %>% dist %>% hclust %>% as.dendrogram
y <- set(x, "labels", 5:1)
dist.dendlist(dendlist(x1 = x,x2 = x,y1 = y))
dend_diff(x,y)
```

---

**distinct_edges**

*Finds distinct edges in one tree compared to another*

**Description**

Finds the edges present in the first tree but not in the second

**Usage**

```r
distinct_edges(dend, dend2, ...)
```

**Arguments**

- `dend` a dendrogram to find unique edges in
- `dend2` a dendrogram to compare with
- `...` Ignored.

**Value**

A numeric vector of edge ids for the first tree (dend) that are not present in the second tree (dend2).

**Source**

A dendrogram implementation for distinct.edges from the distory package

**See Also**
distinct_edges, highlight_distinct_edges, dist.dendlist, tanglegram distinct.edges
Examples

```r
x <- 1:5 %>% dist %>% hclust %>% as.dendrogram
y <- set(x, "labels", 5:1)
distinct_edges(x, y)
distinct_edges(y, x)
dend_diff(x, y)
# tanglegram(x, y)
```

dist_long

*Turns a dist object to a "long" table*

Description

Turns a dist object from a "wide" to a "long" table

Usage

`dist_long(d, ...)`

Arguments

- `d` a distance object
- `...` not used

Value

A data.frame with two columns of rows and column names of the dist object and a third column (distance) with the distance between the two.

Examples

```r
data(iris)
iris[2:6,-5] %>% dist %>% data.matrix
iris[2:6,-5] %>% dist %>% as.vector
iris[2:6,-5] %>% dist %>% dist_long
# This can later be used to making a network plot based on the distances.
```
**duplicate_leaf**

*Duplicate a leaf X times*

**Description**

Duplicates a leaf in a tree. Useful for non-parametric bootstrapping trees since it emulates what would have happened if the tree was constructed based on a row-sample with replacements from the original data matrix.

**Usage**

```
duplicate_leaf(dend, leaf_label, times, fix_members = TRUE, fix_order = TRUE, fix_midpoint = TRUE, ...)```

**Arguments**

- `dend`: a dendrogram object
- `leaf_label`: the label of the leaf to replicate.
- `times`: the number of times we will have this leaf after replication
- `fix_members`: logical (TRUE). Fix the number of members in `attr` using `fix_members_attr.dendrogram`
- `fix_order`: logical (TRUE). Fix the leaves order
- `fix_midpoint`: logical (TRUE). Fix the midpoint value. If TRUE, it overrides "fix_members" and turns it into TRUE (since it must have a correct number of members in order to work). values using `rank_order.dendrogram`
- `...`: not used

**Value**

A dendrogram, after duplicating one of its leaves.

**Examples**

```r
## Not run:
# define dendrogram object to play with:
dend <- USArrests[,1:3,] %>% dist %>% hclust(method = "ave") %>% as.dendrogram
plot(dend)
duplicate_leaf(dend, "Alaska", 3)
duplicate_leaf(dend, "Arizona", 2, fix_members = FALSE, fix_order = FALSE)
plot(duplicate_leaf(dend, "Alaska", 2))
plot(duplicate_leaf(dend, "Alaska", 4))
plot(duplicate_leaf(dend, "Arizona", 2))
plot(duplicate_leaf(dend, "Arizona", 4))
```

## End(Not run)
Measures entanglement between two trees. Entanglement is a measure between 1 (full entanglement) and 0 (no entanglement). The exact behavior of the number depends on the L norm which is chosen.

Usage

```r
entanglement(dend1, ...)  
## S3 method for class 'hclust'
entanglement(dend1, dend2, ...)

## S3 method for class 'phylo'
entanglement(dend1, dend2, ...)

## S3 method for class 'dendlist'
entanglement(dend1, which = c(1L, 2L), ...)

## S3 method for class 'dendrogram'
entanglement(dend1, dend2, L = 1.5,
  leaves_matching_method = c("labels", "order"), ...)
```

Arguments

dend1  
a tree object (of class dendrogram/hclust/phylo).

...  
not used

dend2  
a tree object (of class dendrogram/hclust/phylo).

which  
an integer vector of length 2, indicating which of the trees in a dendlist object should have their entanglement calculated

L  
the distance norm to use for measuring the distance between the two trees. It can be any positive number, often one will want to use 0, 1, 1.5, 2 (see 'details' for more).

leaves_matching_method  
a character scalar, either "order" or "labels" (default). If using "labels", then we use the labels for matching the leaves order value (safer). And if "order" then we use the old leaves order value for matching the leaves order value.

Using "order" is faster, but "labels" is safer. "order" will assume that the original two trees had their labels and order values MATCHED.

Hence, it is best to make sure that the trees used here have the same labels and the SAME values matched to these values - and then use "order" (for fastest results).
Entanglement is measured by giving the left tree's labels the values of 1 till tree size, and than match these numbers with the right tree. Now, entanglement is the L norm distance between these two vectors. That is, we take the sum of the absolute difference (each one in the power of L). e.g: sum(abs(x-y)^L). And this is divided by the "worst case" entanglement level (e.g: when the right tree is the complete reverse of the left tree).

L tells us which penalty level we are at (L0, L1, L2, partial L's etc). L>1 means that we give a big penalty for sharp angles. While L>0 means that any time something is not a straight horizontal line, it gets a large penalty. If L=0.1 it means that we much prefer straight lines over non straight lines.

Value
The number of leaves in the tree

See Also
tanglegram, match_order_by_labels.

Examples

## Not run:
dend1 <- iris[,5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[,5] %>% dist %>% hclust("sin") %>% as.dendrogram
dend12 <- dendlist(dend1, dend2)
tanglegram(dend12)

etanglement(dend12)
etanglement(dend12, L = 0)
etanglement(dend12, L = 0.25)
etanglement(dend1, dend2, L = 0) # 1
etanglement(dend1, dend2, L = 0.25) # 0.97
etanglement(dend1, dend2, L = 1) # 0.93
etanglement(dend1, dend2, L = 2) # 0.88

# a somewhat better tanglegram
tanglegram(sort(dend1), sort(dend2))
# and also a MUCH better entanglement
etanglement(sort(dend1), sort(dend2), L=1.5) # 0.8811
# but not that much, for L=0.25
etanglement(sort(dend1), sort(dend2), L=.25) # 0.579

# massing up the order of leaves is dangerous:
etanglement(dend1, dend2, 1.5, "order") # 0.91
order.dendrogram(dend2) <- seq_len(nleaves(dend2))
# this 0.95 number is NO LONGER correct!!
entanglement(dend1, dend2, 1.5, "order") # 0.95
# but if we use the "labels" method - we still get the correct number:
entanglement(dend1, dend2, 1.5, "labels") # 0.95

# however, we can fix our dend2, as follows:
dend2 <- match_order_by_labels(dend2, dend1)
# Now that labels and order are matched - entanglement is back at working fine:
entanglement(dend1, dend2, 1.5, "order") # 0.95

## End(Not run)

---

fac2num

**Turns a factor into a number**

**Description**

Turning a factor into a number is not trivial. Using `as.numeric` would only return to us the indicator numbers and NOT the factor levels turned into a number. `fac2num` simply turns a factor into a number, as we often need.

**Usage**

`fac2num(x, force_integer = FALSE, keep_names = TRUE, ...)`

**Arguments**

- `x`: an object.
- `force_integer`: logical (FALSE). Should the values returned be integers?
- `keep_names`: logical (TRUE). Should the values returned keep the names of the original vector?
- `...`: ignored.

**Value**

If `x` is an object - it returns logical - is the object of class dendrogram.

**Examples**

```r
x <- factor(3:5)
as.numeric(x) # 1 2 3
fac2num(x) # 3 4 5
```
find_dendrogram

Search for the subdendrogram structure composed of indicated labels

Description

Given a dendrogram object, the function performs a recursive DFS algorithm to determine the
subdendrogram which is composed of all indicated labels. The labels which should compose the
subdendrogram are marked as TRUE in the logical vector of length nleaves(dend)

Usage

find_dendrogram(dend, selected_labels)

Arguments

dend a dendrogram object
selected_labels logical vector with TRUE values at positions of members which should be in-
cluded in the resulting subdendrogram

Value

A subdendrogram composed of only members indicated in the given logical vector clusters.

Examples

```r
## Not run:
define dendrogram object to play with:
dend <- iris[, -5] %>% dist %>% hclust %>% as.dendrogram %>%
set("labels_to_character") %>% color_branches(k=5)
first.subdend.only <- cutree(dend, 4) == 1
sub.dend <- find_dendrogram(dend, first.subdend.only)
# Plotting the result
par(mfrow=c(1,2))
plot(dend, main = "Original dendrogram")
plot(sub.dend, main = "First subdendrogram")
## End(Not run)
```
**find_k**

*Find the (estimated) number of clusters for a dendrogram using average silhouette width*

**Description**

This function estimates the number of clusters based on the maximal average silhouette width derived from running `pam` on the cophenetic distance matrix of the dendrogram. The output is based on the `pamk` output.

**Usage**

```r
find_k(dend, krange = 2:min(10, (nleaves(dend) - 1)), ...)  
## S3 method for class 'find_k'
plot(x, xlab = "Number of clusters (k)",
     ylab = "Average silhouette width",
     main = "Estimating the number of clusters using average silhouette width",
     ...)  
```

**Arguments**

- `dend` A dendrogram (or hclust) tree object
- `krange` integer vector. Numbers of clusters which are to be compared by the average silhouette width criterion. Note: average silhouette width and Calinski-Harabasz can't estimate number of clusters nc=1. If 1 is included, a Duda-Hart test is applied and 1 is estimated if this is not significant.
- `...` passed to `pamk` (the current defaults criterion="asw" and usepam=TRUE can not be changes).
- `x` An object of class "find_k" (has its own S3 plot method).
- `xlab`, `ylab`, `main` parameters passed to `plot`.

**Value**

A `pamk` output. This is a list with the following components: 1) `pamobject` - The output of the optimal run of the `pam`-function. 2) `nc` - the optimal number of clusters. 3) `crit` - vector of criterion values for numbers of clusters. `crit[1]` is the p-value of the Duda-Hart test if 1 is in `krange` and `diss=FALSE`. 4) `k` - a copy of `nc` (just to make it easier to extract - since `k` is often used in other functions)

**See Also**

`pamk`, `pam`, `silhouette`
Examples

```r
dend <- iris[, -5] %>% dist %>% hclust %>% as.dendrogram
dend_k <- find_k(dend)
plot(dend_k)
plot(color_branches(dend, k = dend_k$nc))

library(cluster)
sil <- silhouette(dend_k$pamobject)
plot(sil)

dend <- USArrests %>% dist %>% hclust(method = "ave") %>% as.dendrogram
dend_k <- find_k(dend)
plot(dend_k)
plot(color_branches(dend, k = dend_k$nc))
```

Description

Fix members attr in a dendrogram after (for example), the tree was pruned or manipulated.

Usage

```r
fix_members_attr(dendrogram(dend, ...))
```

Arguments

- **dend**: a dendrogram object
- **...**: not used

Value

A dendrogram, after adjusting the members attr in all of its nodes.

Examples

```r
# define dendrogram object to play with:
hc <- hclust(dist(USArrests[, 1:3]), "ave")
dend <- as.dendrogram(hc)
# plot(dend)
# prune one leaf
dend[[2]] <- dend[[2]][[1]]
# plot(dend)
dend # but it is NO LONGER true that it has 3 members total!
```
flatten.dendrogram

Flatten the branches of a dendrogram’s root

Description
The function makes sure the two branches of the root of a dendrogram will have the same height. The user can choose how to decide which height to use.

Usage
flatten.dendrogram(dend, FUN = max, new_height, ...)

Arguments
- **dend**: dendrogram object
- **FUN**: how to choose the new height of both branches (defaults to taking the max between the two)
- **new_height**: overrides FUN, and sets the new height of the two branches manually
- **...**: passed on (not used)

Value
A dendrogram with both of the root’s branches of the same height

Examples
```r
hc <- hclust(dist(USArrests[1:3,]), "ave")
dend <- as.dendrogram(hc)
identical(prune_leaf(dend, "Alaska"), fix_members_attr.dendrogram(prune_leaf(dend, "Alaska")))
str(unclass(prune_leaf(dend, "Alaska")))
str(unclass(fix_members_attr.dendrogram(prune_leaf(dend, "Alaska"))))
```
**Description**

Rotate a branch in a tree so that the locations of two bundles of leaves are flipped.

**Usage**

`flip_leaves(dend, leaves1, leaves2, ...)`

**Arguments**

- `dend`: a dendrogram object
- `leaves1`: a vector of leaves order value to flip.
- `leaves2`: a (second) vector of leaves order value to flip.
- `...`: not used

**Details**

This function is based on a bunch of string manipulation functions. There may be a smarter/better way for doing it...

**Value**

A dendrogram object with flipped leaves.

**See Also**

tanglegram, match_order_by_labels, entanglement.

**Examples**

```r
## Not run:
dend1 <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram
dend2 <- flip_leaves(dend1, c(3,5), c(1,2))
tanglegram(dend1,dend2)
entanglement(dend1,dend2, L = 2) # 0.4

## End(Not run)
```
Calculating Fowlkes-Mallows Index

Description

Calculating Fowlkes-Mallows index.

As opposed to the `FM_index_profdpm` function, the `FM_index_R` function also calculates the expectancy and variance of the FM Index under the null hypothesis of no relation.

Usage

```r
FM_index(A1_clusters, A2_clusters, include_EV = TRUE,
          assume_sorted_vectors = FALSE, warn = dendextend_options("warn"), ...)
```

Arguments

- `A1_clusters`: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A1. These are often obtained by using some k cut on a dendrogram.
- `A2_clusters`: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A2. These are often obtained by using some k cut on a dendrogram.
- `include_EV`: logical (TRUE). Should we calculate expectancy and variance of the FM Index under null hypothesis of no relation between the clusterings? If TRUE (Default) - then the `FM_index_R` function, else (FALSE) we use the (faster) `FM_index_profdpm` function.
- `assume_sorted_vectors`: logical (FALSE). Can we assume to two group vectors are sorter so that they have the same order of items? IF FALSE (default), then the vectors will be sorted based on their name attribute.
- `warn`: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

Details

From Wikipedia:

Fowlkes-Mallows index (see references) is an external evaluation method that is used to determine the similarity between two clusterings (clusters obtained after a clustering algorithm). This measure of similarity could be either between two hierarchical clusterings or a clustering and a benchmark classification. A higher the value for the Fowlkes-Mallows index indicates a greater similarity between the clusters and the benchmark classifications.
Value
The Fowlkes-Mallows index between two vectors of clustering groups.
Includes the attributes E_FM and V_FM for the relevant expectancy and variance under the null hypothesis of no-relation.

```
Calculating Fowlkes-Mallows Index under H0

**Description**

Calculating Fowlkes-Mallows index under the null hypothesis of no relation between the clusterings (random order of the items labels).

**Usage**

```r
FM_index_permutation(A1_clusters, A2_clusters, 
warn = dendextend_options("warn"), ...) 
```

**Arguments**

- **A1_clusters**: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A1. These are often obtained by using some k cut on a dendrogram.
- **A2_clusters**: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A2. These are often obtained by using some k cut on a dendrogram.
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
- **...**: Ignored (passed to FM_index_R/FM_index_profdpm).

**Value**

The Fowlkes-Mallows index between two vectors of clustering groups. Under H0. (a double without attr)

## End(Not run)
```

Calculating Fowlkes-Mallows index using the profdpm R package
Description

Calculating Fowlkes-Mallows index using the `pci` function from the profdpm R package. This function uses C code (thanks to Matthew Shotwell’s work) and is a bit faster than the R code (from my simple tests - it is about 1.2-1.3 times faster - which is not much but it might be useful).

As opposed to the `FM_index_R` function, the `FM_index_profdpm` function does NOT calculate the expectancy or the variance of the FM Index under the null hypothesis of no relation.

This function also allows us to compare our calculations with an independent writing of a function calculating the same statistic.

Usage

```r
FM_index_profdpm(A1_clusters, A2_clusters, assume_sorted_vectors = FALSE, 
                  warn = dendextend_options("warn"), ...)
```

Arguments

- **A1_clusters**: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A1. These are often obtained by using some k cut on a dendrogram.
- **A2_clusters**: a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A2. These are often obtained by using some k cut on a dendrogram.
- **assume_sorted_vectors**: logical (FALSE). Can we assume to two group vectors are sorter so that they have the same order of items? IF FALSE (default), then the vectors will be sorted based on their name attribute.
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
- **...**: Ignored.

## End(Not run)
```

Description

Calculating Fowlkes-Mallows index.

As opposed to the FM_index_profdpm function, the FM_index_R function also calculates the expectancy and variance of the FM Index under the null hypothesis of no relation.
Usage

FM_index_R(A1_clusters, A2_clusters, assume_sorted_vectors = FALSE, 
warn = dendextend_options("warn"), ...)

Arguments

A1_clusters  a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A1. These are often obtained by using some k cut on a dendrogram.
A2_clusters  a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A2. These are often obtained by using some k cut on a dendrogram.
assume_sorted_vectors logical (FALSE). Can we assume to two group vectors are sorter so that they have the same order of items? IF FALSE (default), then the vectors will be sorted based on their name attribute.
warn logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.
...
... Ignored.

Details

From Wikipedia:

Fowlkes-Mallows index (see references) is an external evaluation method that is used to determine the similarity between two clusterings (clusters obtained after a clustering algorithm). This measure of similarity could be either between two hierarchical clusterings or a clustering and a benchmark classification. A higher the value for the Fowlkes-Mallows index indicates a greater similarity between the clusters and the benchmark classifications.

Value

The Fowlkes-Mallows index between two vectors of clustering groups.

Includes the attributes E_FM and V_FM for the relevant expectancy and variance under the null hypothesis of no-relation.

**get_branches_heights**  
*Get height attributes from a dendrogram*

**Description**

Get height attributes of a dendrogram’s branches

**Usage**

`get_branches_heights(dend, sort = TRUE, decreasing = FALSE, 
include_leaves = FALSE, ...)`

**Arguments**

- `dend`  
a dendrogram.
- `sort`  
logical. Should the heights be sorted?
get_childrens_heights

descending logical. Should the sort be increasing or decreasing? Not available for partial sorting.
include_leaves logical (FALSE). Should the output include the leaves value (0’s).

Value

a vector of the dendrogram’s nodes heights (excluding leaves).

Examples

hc <- hclust(dist(USArrests[1:4,]), "ave")
dend <- as.dendrogram(hc)
get_branches_heights(dend)

gtc childrens_heights

Get height attributes from a dendrogram’s children

Description

Get height attributes from a dendrogram’s children nodes

Usage

get_childrens_heights(dend, ...)

Arguments

dend a dendrogram.
... not used.

Value

a vector of the heights of a dendrogram’s current node’s (first level) children.

See Also

get_branches_heights

Examples

hc <- hclust(dist(USArrests[1:4,]), "ave")
dend <- as.dendrogram(hc)
get_childrens_heights(dend)
**get_leaves_attr**

Get/set attributes of dendrogram’s leaves

### Description

Get/set attributes of dendrogram’s leaves

### Usage

```r
get_leaves_attr(dend, attribute, simplify = TRUE, ...)
```

### Arguments

- `dend`: a dendrogram object
- `attribute`: character scalar of the attribute (attr) we wish to get/set from the leaves
- `simplify`: logical. If TRUE (default), then the return vector is after using `unlist` on it.
- `...`: not used

### Value

A vector (or a list) with the dendrogram’s leaves attribute

### Source

Heavily inspired by the code in the function `labelsNdendrogram`, so credit should go to Martin Maechler.

### See Also

- `get_nodes_attr`, `nnodes`, `nleaves`, `assign_values_to_leaves_nodePar`

### Examples

```r
hc <- hclust(dist(USArrests[1:3, 3]), "ave")
dend <- as.dendrogram(hc)

# get_leaves_attr(dend) # error :
get_leaves_attr(dend, "label")
labels(dend, "label")
get_leaves_attr(dend, "height") # should be 0's
get_nodes_attr(dend, "height")

get_leaves_attr(dend, "nodePar")

get_leaves_attr(dend, "leaf") # should be TRUE's
get_nodes_attr(dend, "leaf") # contains NA's
```
get_leaves_attr(dend, "members") # should be 1's
get_nodes_attr(dend, "members") #

get_leaves_attr(dend, "members", simplify = FALSE) # should be 1's

get_leaves_branches_attr

Get an attribute of the branches of a dendrogram's leaves

Description
This is helpful to get the attributes of branches of the leaves. For example, after we use color_branches, to get the colors of the labels to match (since getting the colors of branches to match those of the labels can be tricky). This is based on get_leaves_edgePar.

Usage
get_leaves_branches_attr(dend, attr = c("col", "lwd", "lty"), ...)

Arguments
dend a dendrogram object
attr character, the attr to get. Can be either "col", "lwd", or "lty".
... not used

Value
A vector with the dendrogram's leaves nodePar attribute

See Also
get_nodes_attr, assign_values_to_leaves_nodePar, labels_colors get_leaves_nodePar, get_leaves_edgePar

Examples
# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)
dend <- dend %>%
   color_branches(k = 3) %>%
   set("branches_lwd", c(2,1,2)) %>%
   set("branches_lty", c(1,2,1))
**get_leaves_branches_col**

get_leaves_branches_col(dend)

get_leaves_branches_attr(dend, "col")
get_leaves_branches_attr(dend, "lwd")
get_leaves_branches_attr(dend, "lty")

labels_colors(dend) <- get_leaves_branches_attr(dend, "col")
plot(dend)

---

**get_leaves_branches_col**

*Get the colors of the branches of a dendrogram’s leaves*

**Description**

It is useful to get the colors of branches of the leaves, after we use `color_branches`, so to then match the colors of the labels to that of the branches (since getting the colors of branches to match those of the labels can be tricky). This is based on `get_leaves_branches_attr` which is based on `get_leaves_edgePar`.

TODO: The function `get_leaves_branches_col` may behave oddly when extracting colors with missing col attributes when the lwd attribute is available. This may result in a vector with the wrong length (with omitted NA values). This might need to be fixed in the future, and attention should be given to this case.

**Usage**

get_leaves_branches_col(dend, ...)

**Arguments**

- `dend` a dendrogram object
- `...` not used

**Value**

A vector with the dendrogram’s leaves’ branches’ colors

**See Also**

`get_nodes_attr`, `assign_values_to_leaves_nodePar`, `labels_colors`, `get_leaves_nodePar`, `get_leaves_edgePar`, `get_leaves_branches_attr`
get_leaves_edgePar

Examples

# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)

par(mfrow = c(1,2), mar = c(5,2,1,0))
dend <- dend %>%
  color_branches(k = 3) %>%
  set("branches_lwd", c(2,1,2)) %>%
  set("branches_lty", c(1,2,1))

plot(dend)

labels_colors(dend) <- get_leaves_branches_col(dend)
plot(dend)

get_leaves_edgePar

Get edgePar of dendrogram’s leaves

Description

This is helpful to get the attributes of branches of the leaves. For example, after we use color_branches,
to get the colors of the labels to match (since getting the colors of branches to match those of the
labels can be tricky).

Usage

get_leaves_edgePar(dend, simplify = FALSE, ...)

Arguments

dend a dendrogram object
simplify logical (default is FALSE). If TRUE, then the return vector is after using unlist
on it.
... not used

Value

A list (or a vector) with the dendrogram’s leaves edgePar attribute

See Also

get_nodes_attr, assign_values_to_leaves_nodePar, labels_colors get_leaves_nodePar
Examples

# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)

# get_leaves_edgePar(dend) # error :)
get_leaves_edgePar(dend)
dend <- color_branches(dend, k = 3)
get_leaves_edgePar(dend)
get_leaves_edgePar(dend, TRUE)

dend <- dend %>% set("branches_lwd", c(2,1,2))
get_leaves_edgePar(dend)
plot(dend)

get_leaves_nodePar  Get nodePar of dendrogram's leaves

Description

Get the nodePar attributes of dendrogram's leaves (includes pch, color, and cex)

Usage

get_leaves_nodePar(dend, simplify = FALSE, ...)

Arguments

dend     a dendrogram object
simplify  logical (default is FALSE). If TRUE, then the return vector is after using unlist on it.
...        not used

Value

A list (or a vector) with the dendrogram’s leaves nodePar attribute

See Also

get_nodes_attr, assign_values_to_leaves_nodePar, labels_colors get_leaves_edgePar
get_nodes_attr

Get attributes of dendrogram's nodes

Description

Allows easy access to attributes of branches and/or leaves, with option of returning a vector with/without NA's (for marking the missing attr value)

Usage

get_nodes_attr(dend, attribute, id, include_leaves = TRUE,
               include_branches = TRUE, simplify = TRUE, na.rm = FALSE, ...)

Arguments

dend a dendrogram object
attribute character scalar of the attribute (attr) we wish to get from the nodes
id integer vector. If given - only the attr of these nodes id will be returned (via depth first search)
include_leaves logical. Should leaves attributes be included as well?
include_branches logical. Should non-leaf (branch node) attributes be included as well?
simplify logical (default is TRUE), should the result be simplified to a vector (using simplify2array) if possible? If it is not possible it will return a matrix. When FALSE, a list is returned.
na.rm logical. Should NA attributes be REMOVED from the resulting vector?
... not used

Examples

# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:3,]), "ave")
dend <- as.dendrogram(hc)

# get_leaves_attr(dend) # error :
get_leaves_nodePar(dend)
labels_colors(dend) <- 1:3
get_leaves_nodePar(dend)

dend <- assign_values_to_leaves_nodePar(dend, 2, "lab.cex")
get_leaves_nodePar(dend)

plot(dend)
**Value**

A vector with the dendrogram’s nodes attribute. If an attribute is missing from some nodes, it will return NA in that vector.

**Source**

Heavily inspired by the code in the function `labels.dendrogram`, so credit should go to Martin Maechler.

**See Also**

`get_leaves_attr`, `nnodes`, `nleaves`

**Examples**

```r
# define dendrogram object to play with:
hc <- hclust(dist(USArrests[,1:3]), "ave")
dend <- as.dendrogram(hc)

# get_leaves_attr(dend) # error :)
get_leaves_attr(dend, "label")
labels(dend, "label")
get_leaves_attr(dend, "height") # should be 0's
get_nodes_attr(dend, "height")

get_leaves_attr(dend, "leaf") # should be TRUE's
get_nodes_attr(dend, "leaf") # contains NA's

get_leaves_attr(dend, "members") # should be 1's
get_nodes_attr(dend, "members", include_branches = FALSE, na.rm = TRUE) #
get_nodes_attr(dend, "members") #
get_nodes_attr(dend, "members", simplify = FALSE)
get_nodes_attr(dend, "members", include_leaves = FALSE, na.rm = TRUE) #

get_nodes_attr(dend, "members", id = c(1,3), simplify = FALSE)
get_nodes_attr(dend, "members", id = c(1,3)) #

hang_dend <- hang.dendrogram(dend)
get_leaves_attr(hang_dend, "height") # no longer 0!
get_nodes_attr(hang_dend, "height") # does not include any 0s!

# does not include leaves values:
get_nodes_attr(hang_dend, "height", include_leaves = FALSE)
# remove leaves values all together:
get_nodes_attr(hang_dend, "height", include_leaves = FALSE, na.rm = TRUE)
```

**## Not run:**
library(microbenchmark)
# get_leaves_attr is twice faster than get_nodes_attr
microbenchmark(
  get_leaves_attr(dend, "members"), # should be 1's
  get_nodes_attr(dend, "members", include_branches = FALSE, na.rm = TRUE)
)

## End(Not run)

definition

get nodes xy

Get the x-y coordinates of a dendogram’s nodes

Description

Get the x-y coordinates of a dendogram’s nodes. Can be used to add text or images on the tree.

Usage

get_nodes_xy(dend, type = c("rectangle", "triangle"), center = FALSE, 
  horiz = FALSE, ...)

Arguments

dend a dendrogram object

type type of plot.

center logical; if TRUE, nodes are plotted centered with respect to the leaves in the 
  branch. Otherwise (default), plot them in the middle of all direct child nodes.

horiz logical indicating if the dendrogram should be drawn horizontally or not.

... not used

Value

A 2-dimensional matrix, with rows as the number of nodes, and the first column is the x location, 
while the second is the y location.

Source

This is a striped down version of the function plot.dendrogram. It performs (almost) the same 
task, only it does not do any plotting but it does save the x-y coordiantes of the nodes.

See Also

get_nodes_attr, nnodes, nleaves
get_root_branches_attr

get attributes from the dendrogram’s root(!) branches

Description

get attributes from the dendrogram’s root(!) branches

Usage

get_root_branches_attr(dend, the_attr, warn = dendextend_options("warn"), ...)

Arguments

dend  dendrogram object
the_attr the attribute to get from the branches (for example "height")
get_subdendrograms

Extract a list of \( k \) subdendrograms from a given dendrogram object

Description

Extracts a list of subdendrogram structures based on the cutree `cutree.dendrogram` function from a given dendrogram object. It can be useful in case of more exact visual investigation of clustering results.

Usage

```r
get_subdendrograms(dend, k, ...)```

Arguments

- `dend`: a dendrogram object
- `k`: the number of subdendrograms that should be extracted
- `...`: parameters that should be passed to the cutree `cutree.dendrogram`

Value

A list of \( k \) subdendrograms, based on the cutree `cutree.dendrogram` clustering clusters.

warn

logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. Should a warning be printed when the function is used on an object which is NOT a dendrogram.

Passed on to attr

Value

The attributes of the branches (often two) of the dendrogram’s root

See Also

`attr`

Examples

```r
hc <- hclust(dist(USArrests[2:9,]), "com")
dend <- as.dendrogram(hc)

get_root_branches_attr(dend, "height") # 0.00000 71.96247
# plot(dend)
str(dend, 2)
```
Examples

# needed packages:
# install.packages(gplots)
# install.packages(viridis)
# install.packages(devtools)
# devtools::install_github('talgalili/dendextend') '
dendextend from github

# define dendrogram object to play with:
dend <- iris[, -5] %>% dist %>% hclust %>% as.dendrogram %>%
  set("labels_to_character") %>% color_branches(k = 5)
dend_list <- get_subdendrograms(dend, 5)

# Plotting the result
par(mfrow = c(2, 3))
plot(dend, main = "Original dendrogram")
sapply(dend_list, plot)

# plot a heatmap of only one of the sub dendrograms
par(mfrow = c(1, 1))
library(gplots)
sub_dend <- dend_list[[1]] ' get the sub dendrogram
# make sure of the size of the dend
nleaves(sub_dend)
length(order.dendrogram(sub_dend))
# get the subset of the data
subset_iris <- as.matrix(iris[order.dendrogram(sub_dend), -5])
# update the dendrogram's internal order so to not cause an error in heatmap.2
order.dendrogram(sub_dend) <- rank(order.dendrogram(sub_dend))
heatmap.2(subset_iris, Rowv = sub_dend, trace = "none", col = viridis::viridis(100))

---

**ggdend**

*Creates dendrogram plot using ggplot.*

Description

Several functions for creating a dendrogram plot using ggplot2. The core process is to transform a
dendrogram into a ggdend object using as.ggdend, and then plot it using ggplot. These two steps
 can be done in one command with either the function ggplot or ggdend.

The reason we want to have as.ggdend (and not only ggplot.dendrogram), is (1) so that you could
create your own mapping of ggdend and, (2) since as.ggdend might be slow for large trees, it is
probably better to be able to run it only once for such cases.

A ggdend class object is a list with 3 components: segments, labels, nodes. Each one contains
the graphical parameters from the original dendrogram, but in a tabular form that can be used by
ggplot2+geom_segment+geom_text to create a dendrogram plot.
Usage

ggdend(...)  
as.ggdend(dend, ...)

## S3 method for class 'dendrogram'
as.ggdend(dend, type = c("rectangle", "triangle"),  
edge.root = FALSE, ...)

prepare.ggdend(data, ...)

## S3 method for class 'ggdend'
ggplot(data, segments = TRUE, labels = TRUE,  
nodes = TRUE, horiz = FALSE, theme = theme_dendro(),  
offset_labels = 0, ...)

## S3 method for class 'dendrogram'
gplot(data, ...)

## S3 method for class 'ggdend'
print(x, ...)

Arguments

... mostly ignored.
dend a dendrogram tree (to be turned into a ggdend object)
type The type of plot, indicating the shape of the dendrogram. "rectangle" will draw rectangular lines, while "triangle" will draw triangular lines.
edge.root currently ignored. One day it might do the following: logical; if true, draw an edge to the root node.
data, x a ggdend class object (passed to ggplot.dendrogram or print.ggdend).
segments a logical (TRUE) if to plot the segments (branches).
lables a logical (TRUE) if to plot the labels.
nodes a logical (TRUE) if to plot the nodes (points).
horiz a logical (TRUE) indicating if the dendrogram should be drawn horizontally or not.
theme the ggplot2 theme to use (default is theme_dendro, can also be NULL for the default ggplot2 theme)
offset_labels a numeric value to offset the labels from the leaves

Details

prepare.ggdend is used by plot.ggdend to take the ggdend object and prepare it for plotting. This is because the defaults of various parameters in dendrogram’s are not always stored in the object itself, but are built-in into the plot.dendrogram function. For example, the color of the labels
is not (by default) specified in the dendrogram (only if we change it from black to something else).
Hence, when taking the object into a different plotting engine (say ggplot2), we want to prepare the
object by filling-in various defaults. This function is automatically invoked within the plot.ggdend
function. You would probably use it only if you’d wish to build your own ggplot2 mapping.

Value

- `as.ggdend` - returns an object of class ggdend which is a list with 3 components: segments,
  labels, nodes. Each one contains the graphical parameters from the original dendrogram, but in
  a tabular form that can be used by ggplot2+geom_segment+geom_text to create a dendrogram
  plot.
- `prepare.ggdend` - a ggdend object (after filling it with various default values)
- `ggplot.ggdend` - a ggplot object

Author(s)

Tal Galili, using code modified from Andrie de Vries

Source

These are extended versions of the functions ggdendrogram, dendro_data (and the hidden dendro-
gram_data) from Andrie de Vries’s ggdendro package. The motivation for this fork is the need to
add more graphical parameters to the plotted tree. This required a strong mixer of functions from
ggdendro and dendextend (to the point that it seemed better to just fork the code into its current
form)

See Also

dendrogram, get_nodes_attr, get_leaves_nodePar, ggplot, ggdendrogram, dendro_data,

Examples

```r
## Not run:

library(dendextend)
# library(ggdendro)
# Create a complex dend:
dend <- iris[1:30,-5] %>% dist %>% hclust %>% as.dendrogram %>%
  set("branches_k_color", k=3) %>% set("branches_lwd", c(1.5,1,1.5)) %>%
  set("branches_lty", c(1,1,3,1,1,2)) %>%
  set("labels_colors") %>% set("labels_cex", c(.9,1.2))
# plot the dend in usual "base" plotting engine:
plot(dend)
# Now let's do it in ggplot2 :) 
ggd1 <- as.ggdend(dend)
library(ggplot2)
ggplot(ggd1) # reproducing the above plot in ggplot2 :) 

labels(dend) <- paste0(labels(dend), "00000")
```
### hang.dendrogram

**Hang dendrogram leaves**

#### Description

Adjust the height attr in all of the dendrogram leaves so that the tree will hang. This is similar to as.dendrogram(hclust, hang=0.1) Only that it now works on other object than hclust turned into a dendrogram. For example, this allows us to hang non-binary trees.

#### Usage

```
hang.dendrogram(dend, hang = 0.1, hang_height, ...)
```
Arguments

- **dend**: a dendrogram object
- **hang**: The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- **hang_height**: is missing, then using "hang". If a number is given, it overrides "hang" (except if "hang" is negative)
- **...**: not used

Value

A dendrogram, after adjusting the height attr in all of its leaves, so that the tree will hang.

Source

Noticing that as.dendrogram has a "hang" parameter was thanks to Enrique Ramos’s answer here::

Examples

```r
# define dendrogram object to play with:
hc <- hclust(dist(USArrests[,1:5]), "ave")
dend <- as.dendrogram(hc)

par(mfrow = c(1,2))
plot(hang.dendrogram(dend))
plot(hc)
# identical(as.dendrogram(hc, hang = 0.1), hang.dendrogram(dend, hang = 0.1))
# TRUE!!

par(mfrow = c(1,4))
plot(dend)
plot(hang.dendrogram(dend, hang = 0.1))
plot(hang.dendrogram(dend, hang = 0))
plot(hang.dendrogram(dend, hang = -0.1))

par(mfrow = c(1,1))
plot(hang.dendrogram(dend), horiz = TRUE)
```
has_component_in_attribute

Does a dendrogram have an edgePar/nodePar component?

Description

Does a dendrogram have an edgePar/nodePar component?

Usage

has_component_in_attribute(dend, component, the_attrib = "edgePar", ...)

Arguments

dend      a dendrogram object.
component a character value to be checked if exists in the tree. For edgePar the list: "col", "lty" and "lwd" (for the segments), "p.col", "p.lwd", and "p.lty" (for the polygon around the text) and "t.col" for the text color. For edgePar "pch", "cex", "col", "xpd", and/or "bg".
the_attrib A character of the attribute for which to check the existence of the component. Often either "edgePar" or "nodePar".
...     ignored

Value

Logical. TRUE if such a component is defined somewhere in the tree, FALSE otherwise. If dend is not a dendrogram, the function will return FALSE.

See Also

get_nodes_attr, set

Examples

dat <- iris[1:20,-5]
hca <- hclust(dist(dat))
hca2 <- hclust(dist(dat), method = "single")
dend <- as.dendrogram(hca)
dend2 <- as.dendrogram(hca2)

dend %>% set("branches_lwd", 2) %>% set("branches_lty", 2) %>% plot
dend %>% set("branches_lwd", 2) %>% set("branches_lty", 2) %>% has_edgePar("lty")
dend %>% set("branches_lwd", 2) %>% has_edgePar("lty")
dend %>% set("branches_lwd", 2) %>% has_edgePar("lwd")

dend %>% set("branches_lwd", 2) %>% set("clear_branches") %>% has_edgePar("lwd")
heights_per_k.dendrogram

Which height will result in which k for a dendrogram

Description

Which height will result in which k for a dendrogram. This helps with speeding up the `cutree.dendrogram` function.

Usage

```r
heights_per_k.dendrogram(dend, ...)
```

Arguments

- `dend` a dendrogram.
- `...` not used.

Value

A vector of heights, with its names being the k clusters that will result for cutting the dendrogram at each height.

Examples

```r
## Not run:
hc <- hclust(dist(USArrests[,1:4]), "ave")
dend <- as.dendrogram(hc)
heights_per_k.dendrogram(dend)
##
##      1   2   3   4
## #86.47086 68.84745 45.98871 28.36531

cutree(hc, h = 68.8) # and indeed we get 2 clusters

unbranch_dend <- unbranch(dend, 2)
plot(unbranch_dend)
heights_per_k.dendrogram(unbranch_dend)
##
##      1   3   4
## #97.90023 57.41808 16.93594
## # we do NOT have a height for k=2 because of the tree's structure.

library(microbenchmark)
dend = as.dendrogram(hclust(dist(iris[,1:150,5])))
dend = as.dendrogram(hclust(dist(iris[,1:30,5])))
dend = as.dendrogram(hclust(dist(iris[,1:3,-5])))
microbenchmark(
  #  dendextendRcpp::heights_per_k.dendrogram(dend),
  dendextendRcpp::dendextendRcpp_heights_per_k.dendrogram(dend),
```
highlight_branches_col

Highlight a dendrogram's branches heights via color and line-width

Description

Highlights (update) the color (col) and/or line width (lwd) of each branch in a dendrogram based on it’s node’s height. This is a powerful pre-processing for a tanglegram plot of two dendrograms, as it emphasizes the topological structure of each tree (and hence, their similarity and differences).

The colors are based on the viridis pallette, and the line width is on the range of 1 to 10. These can be manually changed when using highlight_branches_col and highlight_branches_lwd respectively.

Usage

highlight_branches_col(dend, values = rev(viridis(1000, end = 0.9)), ...)
highlight_branches_lwd(dend, values = seq(1, 10, length.out = 1000), ...)
highlight_branches(dend, type = c("col", "lwd"), ...)

Arguments

dend a dendrogram tree (to be turned into a ggdend object)
values the gradient of values to be used for each branch. The colors are based on the viridis pallette, and the line width is on the range of 1 to 10. These can be manually changed when using highlight_branches_col and highlight_branches_lwd respectively.
...

Currently ignored.
type a character vector. Either "col", "lwd", or both. Based on whichever is chosen the dendrogram’s branches will be updated.

Value

A modified dendrogram, with colors/line-width in the branches that are proportional to each branche’s height (measured by its lower tip).

See Also

set, color_branches, get_branches_heights, viridis
Examples

dat <- iris[1:20, -5]
hca <- hclust(dist(dat))
hca2 <- hclust(dist(dat), method = "single")
dend <- as.dendrogram(hca)
dend2 <- as.dendrogram(hca2)

par(mfrow = c(1, 3))
dend %>% highlight_branches_col %>% plot(main = "Coloring branches")
dend %>% highlight_branches_lwd %>% plot(main = "Emphasizing line-width")
dend %>% highlight_branches %>% plot(main = "Emphasizing color\nand line-width")

library(viridis)
par(mfrow = c(1, 3))
dend %>% highlight_branches_col %>% plot(main = "Coloring branches \n(default is reversed viridis)")
dend %>% highlight_branches_col(viridis(100)) %>%
  plot(main = "It is better to use\nlighter colors in the leaves")
dend %>% highlight_branches_col(rev(magma(1000))) %>%
  plot(main = "The magma color pailatte\nis also good")

dl <- dendlist(dend, dend2)
tanglegram(dl, sort = TRUE, common_subtrees_color_lines = FALSE,
  highlight_distinct_edges = FALSE, highlight_branches_lwd = FALSE)
tanglegram(dl)
tanglegram(dl, fast = TRUE)

dl <- dendlist(highlight_branches(dend), highlight_branches(dend2))
tanglegram(dl, sort = TRUE, common_subtrees_color_lines = FALSE, highlight_distinct_edges = FALSE)

dend %>% set("highlight_branches_col") %>% plot

dl <- dendlist(dend, dend2) %>% set("highlight_branches_col")
tanglegram(dl, sort = TRUE, common_subtrees_color_lines = FALSE, highlight_distinct_edges = FALSE)

# This is also useful for heatmaps
# -----------------------------
# library(dendextend)

x <- as.matrix(datasets::mtcars)

Rowv <- x %>% dist %>% hclust %>% as.dendrogram %>%
  set("branches_k_color", k = 3) %>% set("highlight_branches_lwd") %>%
  ladderize
# rotate_DendSer(ser_weight = dist(x))
Colv <- x %>% t %>% dist %>% hclust %>% as.dendrogram %>%
  set("branches_k_color", k = 2) %>% set("highlight_branches_lwd") %>%
  ladderize
# rotate_DendSer(ser_weight = dist(t(x)))
**highlight_distinct_edges**

*highlight_distinct_edges*

*Highlight distinct edges in a tree (compared to another one)*

**Description**

Highlight distinct edges in a tree (compared to another one) by changing the branches' color, line width, or line type.

This function enables this feature in `dend_diff` and `tanglegram`

**Usage**

```
highlight_distinct_edges(dend, ...) # S3 method for class 'dendrogram'
highlight_distinct_edges(dend, dend2, value = 2,
  edgePar = c("col", "lty", "lwd"), ...)

## S3 method for class 'dendlist'
highlight_distinct_edges(dend, ..., which = c(1L, 2L))
```

**Arguments**

- **dend**: a dendrogram or `dendlist` to find unique edges in (to highlight)
- **...**: Ignored.
- **dend2**: a dendrogram to compare with
- **value**: a new value scalar for the `edgePar` attribute.
- **edgePar**: a character indicating the value inside `edgePar` to adjust. Can be either "col", "lty", or "lwd".
- **which**: an integer vector indicating, in the case "dend" is a dendlist, on which of the trees should the modification be performed. If missing - the change will be performed on all of objects in the dendlist.

**Value**

A dendrogram with modified edges - the distinct ones are changed (color, line width, or line type)

**See Also**

`distinct_edges`, `highlight_distinct_edges`, `dist.dendlist`, `tanglegram`, `assign_values_to_branches_edgePar`, `distinct.edges`,

---

```r
library(gplots)
heatmap.2(x, Rowv = Rowv, Colv = Colv)
```
identify.dendrogram

Identify Clusters in a Dendrogram (not hclust)

Description

Just like identify.hclust: reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

```r
## S3 method for class 'dendrogram'
identify(x, FUN = NULL, N = 20, MAXCLUSTER,
         DEV.FUN = NULL, horiz = FALSE, stop_if_out = FALSE, ...)
```
**Arguments**

- **x**
  - a `dendrogram` object.

- **FUN**
  - (optional) function to be applied to the index numbers of the data points in a cluster (see 'Details' below).

- **N**
  - the maximum number of clusters to be identified.

- **MAXCLUSTER**
  - the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).

- **DEV.FUN**
  - (optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.

- **horiz**
  - logical (FALSE), indicating if the rectangles should be drawn horizontally or not (for when using plot(dend, horiz = TRUE)).

- **stop_if_out**
  - logical (default is FALSE). This default makes the function NOT stop if k of the locator is outside the range (this default is different than the behavior of the `identify.hclust` function - but it is nicer for the user.).

- **...**
  - further arguments to FUN.

**Details**

By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned. If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using `DEV.FUN`. The identification process is terminated by pressing any mouse button other than the first, see also `identify`.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**Source**

This function is based on `identify.hclust`, with slight modifications to have it work with a dendrogram, as well as adding "horiz"

**See Also**

`identify.hclust`, `rect.hclust`, `order.dendrogram`, `cutree.dendrogram`

**Examples**

```r
## Not run:
s.set.seed(23235)
s.s <- sample(1:150, 10)
h.c <- iris[s.s,-5] %>% dist %>% hclust
dend <- h.c %>% as.dendrogram
```
**intersect_trees**

plot(dend)
identify(dend)

plot(dend, horiz = TRUE)
identify(dend, horiz = TRUE)

## End(Not run)

---

**intersect_trees**

**Intersect trees**

**Description**

Return two trees after pruning them so that the only leaves left are the intersection of their labels.

**Usage**

intersect_trees(dend1, dend2, warn = dendextend_options("warn"), ...)

**Arguments**

- **dend1**: tree object (dendrogram/hclust/phylo)
- **dend2**: tree object (dendrogram/hclust/phylo)
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. Should a warning be issued if there was a need to perform intersection.
- ... passed on

**Value**

A dendlist with two pruned trees

**See Also**

prune, intersect, labels

**Examples**

hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)
labels(dend) <- 1:5
dend1 <- prune(dend, 1)
dend2 <- prune(dend, 5)
intersect_dend <- intersect_trees(dend1, dend2)

layout(matrix(c(1,1,2,3,4,5), 3,2, byrow=TRUE))
is.natural.number

Check if numbers are natural

Description

Vectorized function for checking if numbers are natural or not. Helps in checking if a vector is of type "order".

Usage

is.natural.number(x, tol = .Machine$double.eps^0.5, ...)

Arguments

- x: a vector of numbers
- tol: tolerance to floating point issues.
- ...: (not currently in use)

Value

logical - is the entered number natural or not.

Author(s)

Marco Gallotta (a.k.a: marcog), Tal Galili

Source

This function was written by marcog, as an answer to my question here: http://stackoverflow.com/questions/4562257/what-is-the-fastest-way-to-check-if-a-number-is-a-positive-natural-number-in

See Also

is.numeric, is.double, is.integer
is_null_list

Examples

is.natural.number(1) # is TRUE
(x <- seq(-1,5, by=0.5) )
is.natural.number( x )
# is.natural.number("a")
all(is.natural.number( x ))

---

is_null_list  Checks if the value is an empty list()

Description

Checks if the value is an empty list(). Can be useful.

Usage

is_null_list(x)

Arguments

x  whatever object to check

Value

logical

Examples

# I can run this only if I'd make is_null_list exported
## Not run:
## TRUE:
is_null_list(list())
## FALSE
is_null_list(list(1))
is_null_list(1)

x <- list(1, list(), 123)
ss_list <- sapply(x, is_null_list)
x <- x[!ss_list]
x

x <- list(1, list(), 123)
ss_list <- sapply(x, is_null_list)
x <- list(list())
x

## End(Not run)
is_some_class

## Description

Returns TRUE if some class (based on the name of the function).

## Usage

- `is.hclust(x)`
- `is.dendrogram(x)`
- `is.phylo(x)`
- `is.dendlist(x)`
- `is.dist(x)`

### Arguments

- `x` an object.

## Value

Returns TRUE if some class (based on the name of the function).

## Examples

```r
# TRUE:
is.dendlist(dendlist())
# FALSE
is.dendlist(1)
# TRUE:
is.dist(dist(mtcars))
# FALSE
is.dist(mtcars)
```

Description

Usage

khan

Format

Khan is dataset containing the following:

- \$train: data.frame of 306 rows and 64 columns. The training dataset of 64 arrays and 306 gene expression values
- \$test: data.frame, of 306 rows and 25 columns. The test dataset of 25 arrays and 306 genes expression values
- \$gene.labels.imagesID: vector of 306 Image clone identifiers corresponding to the rownames of \$train and \$test.
- \$train.classes: factor with 4 levels "EWS", "BL-NHL", "NB" and "RMS", which correspond to the four groups in the \$train dataset
- \$test.classes: factor with 5 levels "EWS", "BL-NHL", "NB", "RMS" and "Norm" which correspond to the five groups in the \$test dataset
- \$annotation: data.frame of 306 rows and 8 columns. This table contains further gene annotation retrieved from SOURCE http://SOURCE.stanford.edu in May 2004. For each of the 306 genes, it contains:
  - \$CloneID Image Clone ID
  - \$UGCluster The Unigene cluster to which the gene is assigned
  - \$Symbol The HUGO gene symbol
  - \$LLID The locus ID
  - \$UGRepAcc Nucleotide sequence accession number
  - \$LLRepProtAcc Protein sequence accession number
  - \$Chromosome chromosome location
  - \$Cytoband cytoband location
Khan et al., 2001 used cDNA microarrays containing 6567 clones of which 3789 were known genes and 2778 were ESTs to study the expression of genes in four types of small round blue cell tumours of childhood (SRBCT). These were neuroblastoma (NB), rhabdomyosarcoma (RMS), Burkitt lymphoma, a subset of non-Hodgkin lymphoma (BL), and the Ewing family of tumours (EWS). Gene expression profiles from both tumour biopsy and cell line samples were obtained and are contained in this dataset. The dataset downloaded from the website contained the filtered dataset of 2308 gene expression profiles as described by Khan et al., 2001. This dataset is available from http://bioinf.ucd.ie/people/aedin/R/.

In order to reduce the size of the MADE4 package, and produce small example datasets, the top 50 genes from the ends of 3 axes following bga were selected. This produced a reduced datasets of 306 genes.

Source

khan contains a filtered data of 2308 gene expression profiles as published and provided by Khan et al. (2001) on the supplementary web site to their publication http://research.nhgri.nih.gov/microarray/Supplement/.

The data was copied from the made4 package (http://www.bioconductor.org/packages/release/bioc/html/made4.html)

data(khan)
summary(khan)

labels<- "label" assignment operator

Description

"label" assignment operator for vectors, dendrogram, and hclust classes.
Usage

labels(object, ...) <- value

## Default S3 replacement method:
labels(object, ...) <- value

## S3 replacement method for class 'dendrogram'
labels(object, ...) <- value

## S3 method for class 'hclust'
labels(object, order = TRUE, ...)

## S3 replacement method for class 'hclust'
labels(object, ...) <- value

## S3 method for class 'phylo'
labels(object, ...)

## S3 replacement method for class 'phylo'
labels(object, ...) <- value

Arguments

object a variable name (possibly quoted) who's label are to be updated

... parameters passed (not currently in use)

value a value to be assigned to object’s label

order default is FALSE. Only relevant for extracting labels from an hclust object (with labels.hclust). Setting order=TRUE will return labels in their order in the dendrogram, instead of the original labels order retained from object$labels - which usually corresponding to the row or column names of the dist object provided to the hclust function.

Details

###################

Value

The updated object

Author(s)

Gavin Simpson, Tal Galili (with some ideas from Gregory Jefferis’s dendroextras package)

Source

The functions here are based on code by Gavin and kohske from (adopted to dendrogram by Tal Galili): http://stackoverflow.com/questions/4614223/how-to-have-the-following-work-labelsx-some-value Also with some ideas from Gregory Jefferis’s dendroextras package.

labels

Examples

x <- 1:3
labels(x)
labels(x) <- letters[1:3]
labels(x) # [1] "a" "b" "c"
x
# a b c
# 1 2 3

# get("labels<-"

############################
# Example for using the assignment with dendrogram and hclust objects:
hc <- hclust(dist(USArrests[,1:3]), "ave")
dend <- as.dendrogram(hc)

labels(hc) # "Arizona" "Alabama" "Alaska"
labels(hc) <- letters[1:3]
labels(hc) # "A" "B" "C"
labels(dend) # "Arizona" "Alabama" "Alaska"
labels(dend) <- letters[1:3]
labels(dend) # "a" "b" "c"
labels(dend) <- LETTERS[1:2] # will produce a warning
labels(dend) # "A" "B" "A"
labels(dend) <- LETTERS[4:6] # will replace the labels correctly
# (the fact the tree had duplicate labels will not cause a problem)
labels(dend) # "D" "E" "F"

labels_cex

Retrieve/assign cex to the labels of a dendrogram

Description

Retrieve/assign cex to the labels of a dendrogram

Usage

labels_cex(dend, ...)

labels_cex(dend, ...) <- value
Arguments

- **dend**: a dendrogram object
- **value**: a vector of cex to be used as new label's size for the dendrogram

Value

A vector with the dendrogram's labels sizes (NULL if none are supplied).

Examples

```r
# define dendrogram object to play with:
dend <- as.dendrogram(hclust(dist(USArrests[1:3,]), "ave"))

# Defaults:
labels_cex(dend)
plot(dend)

# let's add some color:
labels_cex(dend) <- 1:3
labels_cex(dend)
plot(dend)

labels_cex(dend) <- 1
labels_cex(dend)
plot(dend)
```

labels_colors

Retrieve/assign colors to the labels of a dendrogram

Description

Retrieve/assign colors to the labels of a dendrogram. Note that usually dend objects come without any color assignment (and the output will be NULL, until colors are assigned).

Usage

```r
labels_colors(dend, labels = TRUE, ...)
labels_col(dend, labels = TRUE, ...)
labels_colors(dend, ...) <- value
```
Arguments

- **dend**: a dendrogram object
- **labels**: Boolean (default is TRUE), should the returned vector of colors return with the leaves labels as names.
- **value**: a vector of colors to be used as new label’s colors for the dendrogram

Value

A vector with the dendrogram’s labels colors (or a colored dendrogram, in case assignment is used). The colors are labeled.

Source

Heavily inspired by the code in the example of dendrapply, so credit should go to Martin Maechler. I also implemented some ideas from Gregory Jefferis’s dendroextras package (having the “names” of the returned vector be the labels).

See Also

cutree, dendrogram, hclust, color_labels, color_branches, assign_values_to_leaves_edgePar, get_leaves_branches_col

Examples

```r
# define dendrogram object to play with:
hc <- hclust(dist(USArrests[1:3,]), "ave")
dend <- as.dendrogram(hc)

# Defaults:
labels_colors(dend)
plot(dend)

# let's add some color:
labels_colors(dend) <- 2:4
labels_colors(dend)
plot(dend)

# doesn't work...
# get_nodes_attr(dend, "nodePar", include_branches = FALSE)

# changing color to black
labels_colors(dend) <- 1
labels_colors(dend)
plot(dend)

# removing color (and the nodePar completely – if it has no other attributed but lab.col)
labels_colors(dend) <- NULL
labels_colors(dend)
```
Description
This function reorganizes the internal structure of the tree to get the ladderized effect when plotted.

Usage
ladderize(x, right = TRUE, ...)  
## S3 method for class 'dendrogram'
ladderize(x, right = TRUE, ...)  
## S3 method for class 'phylo'
ladderize(x, right = TRUE, phy, ...)  
## S3 method for class 'dendlist'
ladderize(x, right = TRUE, which, ...)

Arguments
x       a tree object (either a dendrogram, dendlist, or phylo)
right   a logical (TRUE) specifying whether the smallest clade is on the right-hand side (when the tree is plotted upwards), or the opposite (if FALSE).
...     Currently ignored.
phy     a placeholder in case the user uses "phy ="
which   an integer (can have any number of elements). It indicates the elements in the dendlist to ladderize. If missing, it will ladderize all the dendrograms in the dendlist.

Value
A rotated tree object

See Also
ladderize, rev.dendrogram, rotate (dendextend), rotate (ape)
Examples

dend <- USArrests[1:8,]  \%>\% dist \%>\% hclust \%>\% as.dendrogram \%>\% set("labels_colors") \%>\% set("branches_k_color", k = 5)
set.seed(123)
dend <- shuffle(dend)
par(mfrow = c(1,3))
dend \%>\% plot(main = "Original")
dend \%>\% ladderize(TRUE) \%>\% plot(main = "Right (default)")
dend \%>\% ladderize(FALSE) \%>\% plot(main = "Left (rev of right)")

leaf_Colors

Return the leaf Colors of a dendrogram

Description

The returned Colors will be in dendrogram order.

Usage

leaf_Colors(d, col_to_return = c("edge", "node", "label"))

Arguments

d the dendrogram
col_to_return Character scalar - kind of Color attribute to return

Value

named character vector of Colors, NA_character_ where missing

Author(s)

jefferis

See Also

slice, color_branches

Examples

dend <- USArrests \%>\% dist \%>\% hclust(method = "ave") \%>\% as.dendrogram
d5=color_branches(dend, 5)
leaf_Colors(d5)
lowest_common_branch  *Find lowest common branch were the two items are shared*

**Description**

Given two vectors, for two items, of cluster belonging - the function finds the lowest branch (e.g: largest number of k clusters) for which the two items are in the same cluster for the two trees.

**Usage**

```
lowest_common_branch(item1, item2, ...)
```

**Arguments**

- `item1`: a named numeric vector (of cluster group with names of k level)
- `item2`: a named numeric vector (of cluster group with names of k level)
- `...`: not used

**Value**

The first location (from left) where the two vectors have the same A dendrogram, after adjusting the members attr in all of its nodes.

**See Also**

- `cor_bakers_gamma`

**Examples**

```r
item1 <- structure(c(1L, 1L, 1L, 1L), .Names = c("1", "2", "3", "4"))
item2 <- structure(c(1L, 1L, 2L, 2L), .Names = c("1", "2", "3", "4"))
lowest_common_branch(item1, item2)
```

---

match_order_by_labels  *Adjust the order of one dendrogram based on another (using labels)*

**Description**

Takes one dendrogram and adjusts its order leaves valeus based on the order of another dendrogram. The values are matached based on the labels of the two dendrograms. This allows for faster entanglement running time, since we can be sure that the leaves order is just as using their labels.
Usage

match_order_by_labels(dend_change, dend_template,
check_that_labels_match = TRUE)

Arguments

dend_change tree object (dendrogram)
dend_template tree object (dendrogram)
check_that_labels_match logical (TRUE). If to check that the labels in the two dendrogram match. (if they
do not, the function aborts)

Value

Returns dend_change after adjusting its order values to be like dend_template.

See Also

entanglement, tanglegram

Examples

## Not run:

dend <- USArrests[,1:4] %>% dist %>% hclust %>% as.dendrogram
order.dendrogram(dend) # c(4L, 3L, 1L, 2L)

dend_changed <- dend
order.dendrogram(dend_changed) <- 1:4
order.dendrogram(dend_changed) # c(1:4)

# now let's fix the order of the new object to be as it was:
dend_changed <- match_order_by_labels(dend_changed, dend)
# these two are now the same:
order.dendrogram(dend_changed)
order.dendrogram(dend))

## End(Not run)
**Description**

Takes one dendrogram and adjusts its order leaves values based on the order of another dendrogram. The values are matched based on the order of the two dendrograms.

This allows for faster entanglement running time, since we can be sure that the leaves order is just as using their labels.

This is a function is FASTER than `match_order_by_labels`, but it assumes that the order and the labels of the two trees are matching!!

This will allow for a faster calculation of entanglement.

**Usage**

```r
define the function
match_order_dendrogram_by_old_order(dend_change, dend_template, dend_change_old_order, check_that_labels_match = FALSE, check_that_leaves_order_match = FALSE)
```

**Arguments**

- `dend_change`: tree object (dendrogram)
- `dend_template`: tree object (dendrogram)
- `dend_change_old_order`: a numeric vector with the order of leaves in dend_change (at least before it was changes for some reason). This is the vector based on which we adjust the new values of dend_change.
- `check_that_labels_match`: logical (FALSE). If to check that the labels in the two dendrogram match. (if they do not, the function aborts)
- `check_that_leaves_order_match`: logical (FALSE). If to check that the order in the two dendrogram match. (if they do not, the function aborts)

**Value**

Returns dend_change after adjusting its order values to be like dend_template.

**See Also**

`entanglement`, `tanglegram`, `match_order_by_labels`

**Examples**

```r
## Not run:

dend <- USArrests[1:4,] %>% dist %>% hclust %>% as.dendrogram
order.dendrogram(dend) # c(4L, 3L, 1L, 2L)

dend_changed <- dend
```
min_depth

Find minimum/maximum depth of a dendrogram

Description

As the name implies. This can also work for non-dendrogram nested lists.

Usage

min_depth(dend, ...)

max_depth(dend, ...)

Arguments

dend

Any nested list object (including dendrogram).

... unused at the moment.

Value

Integer, the (min/max) number of nodes from the root to the leaves

Examples

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
is.list(dend1)
is.list(dend1[[1]][[1]][[1]])
dend1[[1]][[1]][[1]]
plot(dend1)
min_depth(dend1)
max_depth(dend1)
**na.locf**

*Last Observation Carried Forward*

**Description**

A function for replacing each NA with the most recent non-NA prior to it.

**Usage**

```r
na.locf(x, first_na_value = 0, recursive = TRUE, ...)```

**Arguments**

- `x`: some vector
- `first_na_value`: If the first observation is NA, fill it with "first_na_value"
- `recursive`: logical (TRUE). Should na.locf be re-run until all NA values are filled?
- `...`: ignored.

**Value**

The original vector, but with all the missing values filled by the value before them.

**Source**

This could probably be solved MUCH faster using Rcpp.

**See Also**

`na.locf`

**Examples**

```r
na.locf(c(NA, NA))
na.locf(c(1, NA))
na.locf(c(1, NA, NA, NA))
na.locf(c(1, NA, NA, NA, 2, 2, NA, 3, NA, 4))
na.locf(c(1, NA, NA, NA, 2, 2, NA, 3, NA, 4), recursive = FALSE)
```

```r
# Not run:
library(microbenchmark)
library(zoo)

microbenchmark(
    na.locf = na.locf(c(1, NA, NA, NA, 2, 2, NA, 3, NA, 4)),
    na.locf = na.locf(c(1, NA, NA, NA, 2, 2, NA, 3, NA, 4))
)```
nleaves

Counts the number of leaves in a tree

Description

Counts the number of leaves in a tree (dendrogram or hclust).

Usage

nleaves(x, ...)

## Default S3 method:
nleaves(x, ...)

## S3 method for class 'dendrogram'
nleaves(x, method = c("members", "order"), ...)

## S3 method for class 'dendlist'
nleaves(x, ...)

## S3 method for class 'hclust'
nleaves(x, ...)

## S3 method for class 'phylo'
nleaves(x, ...)

Arguments

- **x**: tree object (dendrogram/hclust/phylo,dendlist)
- **...**: not used
- **method**: a character scalar (default is "members"). If "order" than nleaves is based on length of order.dendrogram. If "members", than length is trusting what is written in the dendrogram’s root attr. "members" is about 4 times faster than "order".

}
**Details**

The idea for the name is from functions like `ncol`, and `nrow`. Also, it is worth noting that the `nleaves.dendrogram` is based on `order.dendrogram` instead of `labels.dendrogram` since the first is MUCH faster than the later. The phylo method is based on turning the phylo to `hclust` and than to dendrogram. It may not work for complex phylo trees.

**Value**

The number of leaves in the tree

**See Also**

`nrow`, `count_terminal_nodes`

**Examples**

```r
hc <- hclust(dist(USArrests[, 1:5]), "ave")
dend <- as.dendrogram(hc)

nleaves(dend) # 5
nleaves(hc) # 5
```

---

<table>
<thead>
<tr>
<th><code>nnodes</code></th>
<th>Counts the number of nodes (Vertices) in a tree</th>
</tr>
</thead>
</table>

**Description**

Counts the number of nodes in a tree (dendrogram, hclust, phylo).

**Usage**

```r
nnodes(x, ...)

## Default S3 method:
nnodes(x, ...)

## S3 method for class 'dendrogram'
nnodes(x, ...)

## S3 method for class 'hclust'
nnodes(x, ...)

## S3 method for class 'phylo'
nnodes(x, ...)
```
\textbf{noded_with_condition}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{x} \hspace{1cm} \text{tree object (dendrogram or hclust)}
  \item \texttt{...} \hspace{1cm} \text{not used}
\end{itemize}

\textbf{Details}

The idea for the name is from functions like ncol, and nrow.
The phylo method is based on turning the phylo to hclust and than to dendrogram. It may not work for complex phylo trees.

\textbf{Value}

The number of leaves in the tree

\textbf{See Also}

nrow, count\_terminal\_nodes, nleaves

\textbf{Examples}

\begin{verbatim}
  hc <- hclust(dist(USArrests[,1:5]), "ave")
  dend <- as.dendrogram(hc)

  nnodes(dend) # 9
  nnodes(hc) # 9
\end{verbatim}

\textbf{Description}

Goes through a tree’s nodes in order to return a vector with whether (TRUE/FALSE) each node satisfies some condition (function)

\textbf{Usage}

\begin{verbatim}
  noded_with_condition(dend, condition, include_leaves = TRUE,
                       include_branches = TRUE, na.rm = FALSE, ...)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{dend} \hspace{1cm} \text{a dendrogram dend}
  \item \texttt{condition} \hspace{1cm} \text{a function that gets a node and return TRUE or FALSE (based on whether or not that node/tree fulfills the "condition")}
  \item \texttt{include\_leaves} \hspace{1cm} \text{logical. Should leaves attributes be included as well?}
  \item \texttt{include\_branches} \hspace{1cm} \text{logical. Should non-leaf (branch node) attributes be included as well?}
\end{itemize}
order.dendrogram

na.rm logical. Should NA attributes be REMOVED from the resulting vector?

Value

A logical vector with TRUE/FALSE, specifying for each of the dendrogram’s nodes if it fulfills the condition or not.

See Also

branches_attr_by_labels, get_leaves_attr, nnodes, nleaves

Examples

## Not run:

library(dendextend)

set.seed(23235)
ss <- sample(1:150, 10 )

# Getting the dend dend
dend <- iris[ss,-5] %>% dist %>% hclust %>% as.dendrogram
dend %>% plot

this is the basis for branches_attr_by_labels
has_any_labels <- function(sub_dend, the_labels) any(labels(sub_dend) %in% the_labels)
cols <- noded_with_condition(dend, has_any_labels,
the_labels = c("126", "109", "59") %>%
ifelse(2,1)
set(dend, "branches_col", cols) %>% plot

# Similar to branches_attr_by_labels - but for heights!
high_enough <- function(sub_dend, height) attr(sub_dend, "height") > height
cols <- noded_with_condition(dend, high_enough, height = 1) %>% ifelse(2,1)
set(dend, "branches_col", cols) %>% plot

## End(Not run)

order.dendrogram<- order.dendrogram<- assignment operator

Description

order.dendrogram<- assignment operator. This is useful in cases where some object is turned into a dendrogram but its leaves values (the order) are all mixed up.
Usage

order.dendrogram(object, ...) <- value

Arguments

object a variable name (possibly quoted) who’s label are to be updated
...

NNN parameters passed (not currently in use)
value a value to be assigned to object’s leaves value (their "order")

Value
dendrogram with updated order leaves values

See Also

order.dendrogram, labels

Examples

# Example for using the assignment with dendrogram and hclust objects:
hc <- hclust(dist(USArrests[1:4,]), "ave")
dend <- as.dendrogram(hc)

str(dend)

order.dendrogram(dend) # 4 3 1 2
order.dendrogram(dend) <- 1:4
order.dendrogram(dend) # 1 2 3 4

str(dend) # the structure is still fine.

# This function is very useful if we try playing with subtrees
# For example:
hc <- hclust(dist(USArrests[1:6,]), "ave")
dend <- as.dendrogram(hc)
sub_dend <- dend[[1]]
order.dendrogram(sub_dend) # 4 6
# now using as.hclust(sub_dend) will cause trouble:
# labels(as.hclust(sub_dend)) # As of R 3.1.1-patched - this will produce an Error (as it should)
# let's fix it:

order.dendrogram(sub_dend) <- rank(order.dendrogram(sub_dend), ties.method= "first")
labels(as.hclust(sub_dend)) # We now have labels :)
order.hclust  

**Ordering of the Leaves in a hclust Dendrogram**

**Description**

Ordering of the Leaves in a hclust Dendrogram. Like order.dendrogram.

**Usage**

```r
order.hclust(x, ...)
```

**Arguments**

- `x`: hclust object a distance matrix.
- `...`: Ignored.

**Value**

A vector with length equal to the number of leaves in the hclust dendrogram is returned. From 
r <- order.hclust(), each element is the index into the original data (from which the hclust was computed).

**See Also**

- order.dendrogram

**Examples**

```r
set.seed(23235)
ss <- sample(1:150, 10)
hc <- iris[ss,-5] %>% dist %>% hclust
# dend <- hc %>% as.dendrogram
order.hclust(hc)
```

---

**partition_leaves**

A list with labels for each subtree (edge)

**Description**

Returns the set of all bipartitions from all edges, that is: a list with the labels for each of the nodes in the dendrogram.

**Usage**

```r
partition_leaves(dend, ...)
```
plot_horiz.dendrogram

Arguments

dend    a dendrogram
...    Ignored.

Value

A list with the labels for each of the nodes in the dendrogram.

Source

A dendrogram implementation for partition.leaves from the distory package

See Also

distinct_edges, highlight_distinct_edges, dist.dendlist, tanglegram, partition.leaves

Examples

x <- 1:3 %>% dist %>% hclust %>% as.dendrogram
plot(x)
partition_leaves(x)

## Not run:
set.seed(23235)
ss <- sample(1:150, 10 )
dend1 <- iris[ss,-5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[ss,-5] %>% dist %>% hclust("single") %>% as.dendrogram

partition_leaves(dend1)
partition_leaves(dend2)

## End(Not run)

plot_horiz.dendrogram  Plotting a left-tip-adjusted horizontal dendrogram

Description

The default plot(dend, horiz = TRUE), gives us a dendrogram tree plot with the tips turned right. The current function enables the creation of the same tree, but with the tips turned left. The main challenge in doing this is finding the distance of the labels from the leaves tips - which is solved with this function.
plot_horiz.dendrogram

Usage

plot_horiz.dendrogram(x, type = c("rectangle", "triangle"), center = FALSE,
edge.root = is.leaf(x) || !is.null(attr(x, "edgetext")), dLeaf = NULL,
horiz = TRUE, xaxt = "n", yaxt = "s", xlim = NULL, ylim = NULL,
nodePar = NULL, edgePar = list(), leaflab = c("perpendicular",
"textlike", "none"), side = TRUE, text_pos = 2, ...)

Arguments

x  
tree object (dendrogram)

<table>
<thead>
<tr>
<th>xtype</th>
<th>a character vector with either &quot;rectangle&quot; or &quot;triangle&quot; (passed to plot.dendrogram)</th>
</tr>
</thead>
<tbody>
<tr>
<td>center</td>
<td>logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.</td>
</tr>
<tr>
<td>edge.root</td>
<td>logical; if true, draw an edge to the root node.</td>
</tr>
<tr>
<td>dLeaf</td>
<td>a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width is used.</td>
</tr>
<tr>
<td>horiz</td>
<td>logical indicating if the dendrogram should be drawn horizontally or not. In this function it MUST be TRUE!</td>
</tr>
<tr>
<td>xaxt</td>
<td>graphical parameters, or arguments for other methods.</td>
</tr>
<tr>
<td>yaxt</td>
<td>graphical parameters, or arguments for other methods.</td>
</tr>
<tr>
<td>xlim</td>
<td>(NULL) optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.</td>
</tr>
<tr>
<td>ylim</td>
<td>(NULL) optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.</td>
</tr>
<tr>
<td>nodePar</td>
<td>NULL.</td>
</tr>
<tr>
<td>edgePar</td>
<td>list().</td>
</tr>
<tr>
<td>leaflab</td>
<td>c(&quot;perpendicular&quot;, &quot;textlike&quot;, &quot;none&quot;)</td>
</tr>
<tr>
<td>side</td>
<td>logical (TRUE). Should the tips of the drawn tree be facing the left side. This is the important feature of this function.</td>
</tr>
<tr>
<td>text_pos</td>
<td>integer from either 1 to 4 (2). Two relevant values are 2 and 4. 2 (default) means that the labels are alligned to the tips of the tree leaves. 4 will have the labels allign to the left, making them look like they were when the tree was on the left side (with leaves tips facing to the right).</td>
</tr>
</tbody>
</table>

Value

The invisiable dLeaf value.

Source

This function is based on replicating plot.dendrogram. In fact, I’d be happy if in the future, some tweaks could be make to plot.dendrogram, so that it would replace the need for this function.
prune

Prunes a tree (using leaves' labels)

Description

Prunes a tree (dendrogram, hclust) from a set of leaves based on their labels.

Usage

prune(dend, ...)

## Default S3 method:
prune(dend, ...)

## S3 method for class 'dendrogram'
prune(dend, leaves, reindex_dend = TRUE, ...)

## S3 method for class 'hclust'
prune(dend, leaves, ...)

## S3 method for class 'phylo'
prune(dend, ...)

See Also

plot.dendrogram, tanglegram

Examples

## Not run:
dend <- USArrests[1:10,] %>% dist %>% hclust %>% as.dendrogram

par(mfrow =c(1,2), mar = rep(6,4))
plot_horiz.dendrogram(dend, side=FALSE)
plot_horiz.dendrogram(dend, side=TRUE)
  # plot_horiz.dendrogram(dend, side=TRUE, dLeaf= 0)
  # plot_horiz.dendrogram(dend, side=TRUE, nodePar = list(pos = 1))
  # sadly, lab.pos is not implemented yet,
  ## so the labels can not be right aligned...

plot_horiz.dendrogram(dend, side=F)
plot_horiz.dendrogram(dend, side=TRUE, dLeaf=0, xlim = c(100,-10)) # bad
plot_horiz.dendrogram(dend, side=TRUE, text_offset = 0)
plot_horiz.dendrogram(dend, side=TRUE, text_offset = 0, text_pos=4)

## End(Not run)
prune

```r
## S3 method for class 'rpart'
prune(dend, ...)
```

### Arguments

- **dend**: tree object (dendrogram/hclust/phylo)
- **leaves**: a character vector of the label(S) of the tip(s) (leaves) we wish to prune off the tree.
- **reindex_dend**: logical (default is TRUE). If TRUE, the leaves of the new dendrograms include the rank of the old order.dendrogram. This insures that their values are just like the number of leaves. When FALSE, the values in the leaves is that of the original dendrogram. This is useful if pruning a dendrogram but then wanting to use `order.dendrogram` with the original values. When using `prune.hclust`, then `reindex_dend` is used by default since otherwise the `as.hclust` function would return an error.

### Details

I was not sure if to call this function `drop.tip` (from ape), `snip/prune` (from rpart) or just `remove.leaves`. I ended up deciding on prune.

### Value

A pruned tree

### See Also

- `prune_leaf`, `drop.tip` ape

### Examples

```r
hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)

par(mfrow = c(1,2))
plot(dend, main = "original tree")
plot(prune(dend, c("Alaska", "California")), main = "tree without Alaska and California")

# this works because prune uses reindex_dend = TRUE by default
as.hclust(prune(dend, c("Alaska", "California")))
prune(hc, c("Alaska", "California"))
```
prune_common_subtrees.dendlist

Prune trees to their common subtrees

Description

Prune trees to their common subtrees

Usage

prune_common_subtrees.dendlist(dend, ...)

Arguments

dend a dendlist of length two

... ignored

Value

A dendlist after pruning the labels to only include those that are part of common subtrees in both dendrograms.

See Also

common_subtrees_clusters

Examples

# NULL

---

prune_leaf

Trims one leaf from a dendrogram

Description

Trims (prunes) one leaf from a dendrogram.

Usage

prune_leaf(dend, leaf_name, ...)
pvclust_edges

Arguments
- dend: dendrogram object
- leaf_name: a character string as the label of the tip we wish to prune
- ...: passed on

Details
Used through prune

Value
A dendrogram with a leaf pruned

Examples
```
hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)

par(mfrow = c(1,2))
plot(dend, main = "original tree")
plot(prune_leaf(dend, "Alaska"), main = "tree without Alaska")
```

---

pvclust_edges  Get Pvclust Edges Information

**Description**
Get pvclust edges information such as au and bp and return dataframe with proper sample labels. This function is useful when there are a lot of samples involved.

**Usage**
pvclust_edges(pvclust_obj)

**Arguments**
- pvclust_obj: pvclust object

**Value**
data.frame with leaves on column 1 and 2, followed by the rest of the information from edge

**References**
Examples

```r
## Not run:

library(pvclust)
data(lung) # 916 genes for 73 subjects
set.seed(13134)
result <- pvclust(lung[1:20], method.dist="cor", method.hclust="average", nboot=100)
pvclust_edges(result)
```

## End(Not run)

---

**pvclust_show_signif**  
*The significant branches in a dendrogram, based on a pvclust object*

---

Description

Shows the significant branches in a dendrogram, based on a pvclust object

Usage

```r
pvclust_show_signif(dend, pvclust_obj, signif_type = c("bp", "au"),
alpha = 0.05, signif_value = c(5, 1), show_type = c("lwd", "col"), ...)
```

Arguments

- `dend`: a dendrogram object
- `pvclust_obj`: a pvclust object
- `signif_type`: a character scalar (either "bp" or "au"), indicating which of the two should be used to update the dendrogram.
- `alpha`: a number between 0 to 1, default is .05. Indicates what is the cutoff from which branches will be updated.
- `signif_value`: a 2d vector (default: c(5,1)), with the first element tells us what the significant branches will get, and the second element which value the non-significant branches will get.
- `show_type`: a character scalar (either "lwd" or "col"), indicating which parameter of the branches should be updated based on significance.
- `...`: not used

Value

A dendrogram with updated branches

See Also

`pvclust_show_signif, pvclust_show_signif_gradient`
pvclust_show_signif_gradient

Significance gradient of branches in a dendrogram (via pvclust)

Description

Shows the gradient of significance of branches in a dendrogram, based on a pvclust object

Usage

pvclust_show_signif_gradient(dend, pvclust_obj, signif_type = c("bp", "au"),
  signif_col_fun = colorRampPalette(c("black", "darkred", "red")), ...)

Arguments

dend          a dendrogram object
pvclust_obj   a pvclust object
signif_type   a character scalar (either "bp" or "au"), indicating which of the two should be used to update the dendrogram.
signif_col_fun a function to create colors for the significant gradient. Default is: colorRampPalette(c("black", "darkred", "red"))

... not used

Value
A dendrogram with updated branches

See Also
pvclust_show_signif, pvclust_show_signif_gradient

Examples

```r
## Not run:
library(pvclust)
data(lung) # 916 genes for 73 subjects
set.seed(13134)
result <- pvclust(lung[, 1:20], method.dist="cor", method.hclust="average", nboot=100)
dend <- as.dendrogram(result)
result %>% as.dendrogram %>%
  hang.dendrogram %>%
  plot(main = "Cluster dendrogram with AU/BP values (%)")
result %>% text
result %>% pvrect(alpha=0.95)
dend %>% pvclust_show_signif(result) %>% plot
dend %>% pvclust_show_signif(result, show_type = "lwd") %>% plot
result %>% text
result %>% pvrect(alpha=0.95)
dend %>% pvclust_show_signif_gradient(result) %>% plot
dend %>%
  pvclust_show_signif_gradient(result) %>%
  pvclust_show_signif(result) %>%
  plot(main = "Cluster dendrogram with AU/BP values (%)\nbp values are highlighted by signif")
result %>% text
result %>% pvrect(alpha=0.95)
## End(Not run)
```

---

**pvrect2**

*Draw Rectangles Around a Dendrogram's Clusters with High/Low P-values*

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters with low p-values. This is based on *pvrect*, allowing to draw the rects till the bottom of the labels.
Usage

pvrect2(x, alpha = 0.95, pv = "au", type = "geq", max.only = TRUE,
border = 2, xpd = TRUE, lower_rect, ...)

Arguments

x
  object of class pvclust.
alpha
  threshold value for p-values., Default: 0.95
pv
  character string which specifies the p-value to be used. It should be either of "au"
or "bp", corresponding to AU p-value or BP value, respectively. See plot.pvclust
  for details. , Default: 'au'
type
  one of "geq", "leq", "gt" or "lt". If "geq" is specified, clusters with p-value
  greater than or equals the threshold given by "alpha" are returned or displayed.
  Likewise "leq" stands for lower than or equals, "gt" for greater than and "lt" for
  lower than the threshold value. The default is "geq"., Default: 'geq'
max.only
  logical. If some of clusters with high/low p-values have inclusion relation, only
  the largest cluster is returned (or displayed) when max.only=TRUE., Default: TRUE
border
  numeric value which specifies the color of borders of rectangles., Default: 2
xpd
  A logical value (or NA.), passed to par. Default is TRUE, in order to allow the
  rect to be below the labels. If FALSE, all plotting is clipped to the plot region,
  if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is
  clipped to the device region. See also clip., Default: TRUE
lower_rect
  a (scalar) value of how low should the lower part of the rect be. If missing, it will
take the value of par("usr")[3L] (or par("usr")[2L], depending if horiz = TRUE
or not), with also the width of the labels. (notice that we would like to keep xpd
  = TRUE if we want the rect to be after the labels!) You can use a value such as
  0, to get the rect above the labels.
...
  passed to rect

See Also

pvrect, pvclust_show_signif

Examples

## Not run:

c1 <- pvrect2(lung[, 1:20], method.dist="cor", method.hclust="average", nboot=10)
c2 <- pvclustShowSignif(lung[, 1:20], method.dist="cor", method.hclust="average", nboot=10)
pvrect2(lung[1:20,], method.dist="cor", method.hclust="average", nboot=10)
raise.dendrogram

Description

Raise the height of nodes in a dendrogram tree.

Usage

```r
raise.dendrogram(dend, height_to_add, ...)
```

Arguments

- `dend`: dendrogram object
- `height_to_add`: how much height to add to all the branches (not leaves) in the dendrogram
- `...`: passed on (not used)

Value

A raised dendrogram

Examples

```r
hc <- hclust(dist(USArrests[2:9,]), "com")
dend <- as.dendrogram(hc)

par(mfrow = c(1,2))
plot(dend, main = "original tree")
plot(raise.dendrogram(dend, 100), main = "Raised tree")
```
**rank_branches**

**Rank branches**' heights

---

**Description**

Adjust the height attr in all of the dendrogram nodes so that the tree will have a distance of 1 unit between each parent/child nodes. It can be thought of as ranking the branches between themselves.

This is intended for easier comparison of the topology of two trees.

Notice that this function changes the height of all the leaves into 0, thus erasing the effect of `hang.dendrogram` (which should be run again, if that is the visualization you are interested in).

**Usage**

```r
rack_branches(dend, diff_height = 1, ...)
```

**Arguments**

- **dend**: a dendrogram object
- **diff_height**: Numeric scalar (1). Affects the difference in height between two branches.
- **...**: not used

**Value**

A dendrogram, after adjusting the height attr in all of its branches.

**See Also**

- `get_branches_heights`
- `get_childrens_heights`
- `hang.dendrogram`
- `tanglegram`

**Examples**

```r
# define dendrogram object to play with:
dend <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram

par(mfrow = c(1,3))

plot(dend)
plot(rank_branches(dend))
plot(hang.dendrogram(rank_branches(dend)))
```
rank_order.dendrogram  Fix rank of leaves order values in a dendrogram

Description

Generally, leaves order value should be a sequence of integer values. From 1 to nleaves(dend). This function fixes trees by using rank on existing leaves order values.

Usage

rank_order.dendrogram(dend, ...)

Arguments

dend    a dendrogram object
...    not used

Value

A dendrogram, after fixing its leaves order values.

See Also

prune

Examples

# define dendrogram object to play with:
dend <- USArrests[1:4,] %>% dist %>% hclust(method = "ave") %>% as.dendrogram
# plot(dend)
order.dendrogram(dend)
dend2 <- prune(dend, "Alaska")
order.dendrogram(dend2)
order.dendrogram(rank_order.dendrogram(dend2))

rank_values_with_clusters

Rank a vector based on clusters

Description

Rank a vector based on clusters
rect.dendrogram

Usage

rank_values_with_clusters(x, ignore0 = FALSE, ...)

Arguments

x numeric vector
ignore0 logical (FALSE). If TRUE, will ignore the 0’s in the vector
... not used

Value

an integer vector with the number of unique values as the number of uniques in the original vector. And the values are ranked from 1 (in the beginning of the vector) to the number of unique clusters.

Examples

rank_values_with_clusters(c(1,2,3))
rank_values_with_clusters(c(1,1,3))
rank_values_with_clusters(c(0,1,0,1,3000))
rank_values_with_clusters(c(3,1,2))
rank_values_with_clusters(c(1,3,3,3,3,3,4,2,2))

rect.dendrogram

Draw Rectangles Around a Dendrogram's Clusters

Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

Usage

rect.dendrogram(tree, k = NULL, which = NULL, x = NULL, h = NULL, border = 2, cluster = NULL, horiz = FALSE, density = NULL, angle = 45, text = NULL, text_cex = 1, text_col = 1, xpd = TRUE, lower_rect, upper_rect = 0, prop_k_height = 0.5, stop_if_out = FALSE, ...)

rect.dendrogram

Arguments

tree  
a dendrogram object.

k      
Scalar. Cut the dendrogram such that exactly k clusters (if possible) are produced.

which  
A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree). Default is which = 1:k.

x      
A vector selecting the clusters around which a rectangle should be drawn. x selects clusters containing the respective horizontal coordinates.

h      
Scalar. Cut the dendrogram by cutting at height h. (k overrides h)

border 
Vector with border colors for the rectangles.

cluster 
Optional vector with cluster memberships as returned by cutree(dend_obj, k = k), can be specified for efficiency if already computed.

horiz 
logical (FALSE), indicating if the rectangles should be drawn horizontally or not (for when using plot(dend, horiz = TRUE)).

density 
Passed to rect: the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling). If border is a vector of colors, the color of density will default to 1.

angle  
Passed to rect: angle (in degrees) of the shading lines. (default is 45)

text 
a character vector of labels to plot underneath the clusters. When NULL (default), no text is displayed.

text_cex 
a numeric (scalar) value of the text's cex value.

text_col 
a (scalar) value of the text's col(or) value.

xpd    
A logical value (or NA.), passed to par. Default is TRUE, in order to allow the rect to be below the labels. If FALSE, all plotting is clipped to the plot region, if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is clipped to the device region. See also clip.

lower_rect  
a (scalar) value of how low should the lower part of the rect be. If missing, it will take the value of par("usr")[3L] (or par("usr")[2L], depending if horiz = TRUE or not), with also the width of the labels. (notice that we would like to keep xpd = TRUE if we want the rect to be after the labels!) You can use a value such as 0, to get the rect above the labels.

Notice that for a plot with small margins, it would be better to set this parameter manually.

upper_rect  
a (scalar) value to add (default is 0) to how high should the upper part of the rect be.

prop_k_height  
a (scalar) value (should be between 0 to 1), indicating what proportion of the height our rect will be between the height needed for k and k+1 clustering.

stop_if_out  
logical (default is TRUE). This makes the function stop if k of the locator is outside the range (this default reproduces the behavior of the rect.hclust function).

...  
parameters passed to rect (such as lwd, lty, etc.)
**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**Source**

This function is based on `rect.hclust`, with slight modifications to have it work with a dendrogram, as well as a few added features (e.g: ... to rect, and horiz)

The idea of adding text and shading lines under the clusters comes from skullkey from here: [http://stackoverflow.com/questions/4720307/change-dendrogram-leaves](http://stackoverflow.com/questions/4720307/change-dendrogram-leaves)

**See Also**

`rect.hclust`, `order.dendrogram`, `cutree.dendrogram`

**Examples**

```r
current.seed <- sample(1:10, 10)
hr <- iris[current.seed, -5] dist <- hclust
dend <- hr as.dendrogram

plot(dend)
rect.dendrogram(dend, border = 2)
rect.dendrogram(dend, border = 5)
Vectorize(rect.dendrogram, "k")

plot(dend)
rect.dendrogram(dend, border = 1:3,

density = 2, text = c("1", "b", "miao"), text_cex = 3)

plot(dend)
rect.dendrogram(dend, which = c(1,3), border = c(2,3))
rect.dendrogram(dend, x = 5, border = c(4))
rect.dendrogram(dend, border = 3, lwd = 2, lty = 2)
# now THIS, you can not do with the old rect.hclust
plot(dend, horiz = TRUE)
rect.dendrogram(dend, border = 2, horiz = TRUE)
rect.dendrogram(dend, 4, border = 4, lty = 2, lwd = 3, horiz = TRUE)

# This had previously failed since it worked with a wrong k.
dend15 <- c(1:5) dist <- hclust(method = "average") as.dendrogram
# dend15 <- c(1:25) dist <- hclust(method = "average") as.dendrogram
dend15 branches_k_color

dend15 rect.dendrogram(k = 3,

border = 8, lty = 5, lwd = 2)
```
Description

prune_leaf does not update leaf indices as it prune leaves. As a result, some leaves of the pruned dendrogram may have leaf indeces larger than the number of leaves in the pruned dendrogram, which may cause errors in downstream functions such as as.hclust.

This function re-indexes the leaves such that the leaf indices are no larger than the total number of leaves.

Usage

reindex_dend(dend)

Arguments

dend dendrogram object

Value

A dendrogram object with the leaf reindexed

Examples

hc <- hclust(dist(USArrests[1:5,]), "ave")
dend <- as.dendrogram(hc)

dend_pruned <- prune(dend, c("Alaska", "California"), reindex_dend = FALSE )

## A leave have an index larger than the number of leaves:
unlist (dend_pruned)
# [1] 4 3 1
##
dend_pruned_reindexed <- reindex_dend (dend_pruned)

## All leaf indices are no larger than the number of leaves:
unlist (dend_pruned_reindexed)
# [1] 3 2 1

## The dendrograms are equal:
all.equal (dend_pruned, dend_pruned_reindexed)
# TRUE
**remove_branches_edgePar**

*Remove all edgePar values from a dendrogram’s branches*

**Description**

Go through the dendrogram branches and remove its edgePar.

**Usage**

```r
remove_branches_edgePar(dend, ...)
```

**Arguments**

- `dend` a dendrogram object
- `...` not used

**Value**

A dendrogram, after removing the edgePar attribute in all of its branches,

**See Also**

`get_root_branches_attr`, `assign_values_to_branches_edgePar`

**Examples**

```r
## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram
dend <- color_branches(dend, 3)
par(mfrow = c(1,2))
plot(dend)
plot(remove_branches_edgePar(dend))

## End(Not run)
```
remove_leaves_nodePar

Remove all nodePar values from a dendrogram's leaves

Description

Go through the dendrogram leaves and remove its nodePar.

Usage

remove_leaves_nodePar(dend, ...)

Arguments

dend a dendrogram object

... not used

Value

A dendrogram, after removing the nodePar attribute in all of its leaves.

See Also

get_leaves_attr, assign_values_to_leaves_nodePar

Examples

## Not run:

dend <- USArrests[1:5,] %>% dist %>% hclust %>% as.dendrogram

dend <- color_labels(dend, 3)
par(mfrow = c(1,2))
plot(dend)
plot(remove_leaves_nodePar(dend))

get_leaves_attr(dend, "nodePar")
get_leaves_attr(remove_leaves_nodePar(dend), "nodePar")

## End(Not run)
remove_nodes_nodePar

Remove all nodePar values from a dendrogram’s nodes

Description

Go through the dendrogram nodes and remove its nodePar

Usage

remove_nodes_nodePar(dend, ...)

Arguments

dend a dendrogram object
...
not used

Value

A dendrogram, after removing the nodePar attribute in all of its nodes,

See Also

get_root_branches_attr, assign_values_to_branches_edgePar

Examples

## Not run:

dend <- USArrests[1:5,] dist hclust as.dendrogram
dend <- color_branches(dend, 3)
par(mfrow = c(1,2))
plot(dend)
plot(remove_branches_edgePar(dend))

## End(Not run)
rllply

recursivly apply a function on a list

Description

recursivly apply a function on a list - and returns the output as a list, following the naming convention in the plyr package the big difference between this and rapply is that this will also apply the function on EACH element of the list, even if it's not a "terminal node" inside the list tree. An attribute is added to indicate if the value returned is from a branch or a leaf.

Usage

rllply(x, FUN, add_notation = FALSE, ...)

Arguments

x
a list.

FUN
a function to apply on each element of the list

add_notation
logical. Should each node be added a "position_type" attribute, stating if it is a "Branch" or a "Leaf".

... not used.

Value

a list with ALL of the nodes (from the original "x" list), that FUN was applied on.

Examples

```r
## Not run:
x <- list(1)
x
rllply(x, function(x)(x), add_notation = TRUE)

x <- list(1, 2, list(3))
x
rllply(x, function(x)(x), add_notation = TRUE)
  # the first element is the entire tree
  # after FUN was applied to its root element.

hc <- hclust(dist(USArrests[1:4,]), "ave")
dend <- as.dendrogram(hc)
rllply(dend, function(x)(attr(x, "height")))
rllply(dend, function(x)(attr(x, "members")))

## End(Not run)
```
Description
Rotates, rev and sort the branches of a tree object (dendrogram, hclust) based on a vector - either of labels order (numbers) or the labels in their new order (character).

Usage
rotate(x, ...)

## Default S3 method:
rotate(x, order, ...)

## S3 method for class 'dendrogram'
rotate(x, order, ...)

## S3 method for class 'hclust'
rotate(x, order, ...)

## S3 method for class 'phylo'
rotate(x, ..., phy)

## S3 method for class 'dendrogram'
sort(x, decreasing = FALSE, type = c("labels", "nodes"), ...)

## S3 method for class 'hclust'
sort(x, decreasing = FALSE, ...)

## S3 method for class 'dendlist'
sort(x, ...)

## S3 method for class 'hclust'
rev(x, ...)

Arguments
- x a tree object (either a dendrogram or hclust)
- ... parameters passed (for example, in case of sort)
- order Either numeric or character vector. Is numeric: it is a numeric vector with the order of the value to be assigned to object’s label. The numbers say are just like when you use order: which of the items on the tree-plot should be "first" (e.g: most left), second etc. (this is relevant only to rotate) Is character: it must be a vector with the content of labels(x), in the order we’d like to have the new tree.
phy a placeholder in case the user uses "phy ="
decreasing logical. Should the sort be increasing or decreasing? Not available for partial sorting. (relevant only to sort)
type a character indicating how to sort. If "labels" then by lexicographic order of the labels. If "nodes", then by using ladderize (order so that recursively, the leftmost branch will be the smallest)

Details
The motivation for this function came from the function order.dendrogram NOT being very intuitive. What rotate aims to do is give a simple tree rotation function which is based on the order which the user would like to see the tree rotated by (just as order works for numeric vectors).

rev.dendrogram is part of base R, and returns the tree object after rotating it so that the order of the labels is reversed. Here we added an S3 method for hclust objects.
The sort methods sort the labels of the tree (using order) and then attempts to rotate the tree to fit that order.
The hclust method of "rotate" works by first changing the object into dendrogram, performing the rotation, and then changing it back to hclust. Special care is taken in preserving some of the properties of the hclust object.
The ape package has its own rotate(ape) function (Which is sadly not S3, so cannot be easily connected with the current implementation). Still, there is an S3 plug that makes sure people loading first ape and then dendextend will still be able to use rotate without a problem. Notice that if you will first load ape and only then dendextend, using "rotate" will fail with the error: "Error in rotate(dend, ____): object "phy" is not of class "phylo" - this is because rotate in ape is not S3 and will fail to find the rotate.dendrogram function. In such a case simply run unloadNamespace(ape). Or, you can run: unloadNamespace("dendextend"); attachNamespace("dendextend") The solution for this is that if you have ape installed on your machine, It will be loaded when you load dendextend (but after it). This way, rotate will work fine for both dendrogram AND phylo objects.

Value
A rotated tree object

See Also
order.dendrogram, order, rev.dendrogram, rotate (ape), ladderize

Examples
hc <- hclust(dist(USArrests[c(1,6,13,20, 23),]), "ave")
dend <- as.dendrogram(hc)

# For dendrogram objects:
labels_colors(dend) <- rainbow(nleaves(dend))
# let's color the labels to make the followup of the rotation easier
par(mfrow = c(1,2))
plot(dend, main = "Original tree")
plot(rotate(dend, c(2:5,1)), main =
"Rotates the left most leaf \n into the right side of the tree")
par(mfrow = c(1,2))
plot(dend, main = "Original tree")
plot(sort(dend), main = "Sorts the labels by alphabetical order \n and rotates the tree to give the best fit possible")
par(mfrow = c(1,2))
plot(dend, main = "Original tree")
plot(rev(dend), main = "Reverses the order of the tree labels")

# For hclust objects:
plot(hc)
plot(rotate(hc, c(2:5,1)), main = "Rotates the left most leaf \n into the right side of the tree")

par(mfrow = c(1,3))
dend %>% plot(main = "Original tree")
dend %>% sort %>% plot(main = "labels sort")
dend %>% sort(type = "nodes") %>% plot(main = "nodes (ladderize) sort")

rotate_DendSer  Rotates dend based on DendSer

Description

Rotates a dendrogram based on its seriation

The function tries to turn the dend into hclust using DendSer.dendrogram (based on DendSer)
Also, if a distance matrix is missing, it will try to use the cophenet distance.

Usage

rotate_DendSer(dend, ser_weight, ...)

Arguments

dend  An object of class dendrogram
ser_weight  Used by cost function to evaluate ordering. For cost=costLS, this is a vector of object weights. Otherwise is a dist or symmetric matrix. passed to DendSer.dendrogram and from there to DendSer.
If it is missing, the cophenetic distance is used instead.
...

Value

Numeric vector giving an optimal dendrogram order
See Also

DendSer, DendSer.dendrogram, untangle_DendSer, rotate_DendSer

Examples

```
## Not run:
library(DendSer)  # already used from within the function
dend <- USArrests[1:4,] %>% dist %>% hclust("ave") %>% as.dendrogram
DendSer.dendrogram(dend)

tanglegram(dend, rotate_DendSer(dend))
```

## End(Not run)

---

### sample.dendrogram

**Sample a tree**

#### Description

Samples a tree, either by permuting the labels (which is useful for a permutation test), or by repeated sampling of the same labels (essential for bootstrapping when we don’t have access to the original data which produced the tree).

Duplicates a leaf in a tree. Useful for non-parametric bootstrapping trees since it emulates what would have happened if the tree was constructed based on a row-sample with replacements from the original data matrix.

#### Usage

```
sample.dendrogram(dend, replace = FALSE, dend_labels, sampled_labels,
                  fix_members = TRUE, fix_order = TRUE, fix_midpoint = TRUE, ...)
```

#### Arguments

- **dend**
  a dendrogram object

- **replace**
  logical (FALSE). Should we shuffle the labels (if FALSE), or should we replicate the same leaf over and over, while omitting other leaves? (this is when set to TRUE).

- **dend_labels**
  a character vector of the tree’s labels. This can save the time it takes for getting the tree labels (in case we run a simulating, computing this once might save some running time). If missing, it uses `labels` in order to get the labels.

- **sampled_labels**
  a character vector of the tree’s sampled labels. This can help us if we wish to compare two trees. In such a case we’d like to be able to have the same sample of labels used on both trees. If missing, it uses `sample` in order to get the sampled labels.

  Only works when `replace=TRUE`!
Rotates a dendrogram based on a seriation of a distance matrix

Description

Rotates a dendrogram so it confirms to an order of a provided distance object. The seriation algorithm is based on \texttt{seriate}, which tries to find a linear order for objects using data in form of a dissimilarity matrix (one mode data).

This is useful for heatmap visualization.

Usage

\texttt{seriate_dendrogram(dend, x, method = c("OLO", "GW"), ...)}

set

set (/update) features to a dendrogram

Description

a master function for updating various attributes and features of dendrogram objects.

Usage

set(dend, ...)

## S3 method for class 'dendrogram'
set(dend, what = c("labels", "labels_colors", "method"), ...)
"labels_cex", "labels_to_character", "leaves_pch", "leaves_cex", "leaves_col", "nodes_pch", "nodes_cex", "nodes_col", "hang_leaves", "rank_branches", "branches_k_color", "branches_k_lty", "branches_col", "branches_lwd", "branches_lty", "by_labels_branches_col", "by_labels_branches_lwd", "by_labels_branches_lty", "by_lists_branches_col", "by_lists_branches_lwd", "by_lists_branches_lty", "highlight_branches_col", "highlight_branches_lwd", "clear_branches", "clear_leaves"), value, order_value = FALSE, ...)

## S3 method for class 'dendlist'
set(dend, ..., which)

## S3 method for class 'data.table'
set(...)

Arguments

dend a tree (dendrogram, or dendlist)

... passed to the specific function for more options.

what a character indicating what is the property of the tree that should be set/updated. (see the usage and the example section for the different options)

value an object with the value to set in the dendrogram tree. (the type of the value depends on the "what")

order_value logical. Default is FALSE. If TRUE, it means the order of the value is in the order of the data which produced the hclust or dendrogram - and will reorder the value to conform with the order of the labels in the dendrogram.

which an integer vector indicating, in the case "dend" is a dendlist, on which of the trees should the modification be performed. If missing - the change will be performed on all of dends in the dendlist.

Details

This is a wrapper function for many of the main tasks we might wish to perform on a dendrogram before plotting.

The options of by_labels_branches_col, by_labels_branches_lwd, by_labels_branches_lty have extra parameters: type, attr, TF_value, and by_lists_branches_col, by_lists_branches_lwd, by_lists_branches_lty have extra parameters: attr, TF_value. You can read more about them here: branches_attr_by_labels and branches_attr_by_lists

The "what" parameter can accept the following options:

- labels - set the labels (labels<-dendrogram)
- labels_colors - set the labels’ colors (color_labels)
- labels_cex - set the labels’ size (assign_values_to_leaves_nodePar)
- labels_to_character - set the labels’ to be characters
- leaves_pch - set the leaves’ point type (assign_values_to_leaves_nodePar). A leave is the terminal node of the tree.
• leaves_cex - set the leaves’ point size (assign_values_to_leaves_nodePar). For using this you MUST also set leaves_pch, a good value to use is 19.
• leaves_col - set the leaves’ point color (assign_values_to_leaves_nodePar). For using this you MUST also set leaves_pch, a good value to use is 19.
• nodes_pch - set the nodes’ point type (assign_values_to_nodes_nodePar)
• nodes_cex - set the nodes’ point size (assign_values_to_nodes_nodePar)
• nodes_col - set the nodes’ point color (assign_values_to_nodes_nodePar)
• hang_leaves - hang the leaves (hang.dendrogram)
• branches_k_color - color the branches (color_branches), a k parameter needs to be supplied.
• branches_k_lty - updates the lwd of the branches (similar to branches_k_color), a k parameter needs to be supplied.
• branches_col - set the color of branches (assign_values_to_branches_edgePar)
• branches_lwd - set the line width of branches (assign_values_to_branches_edgePar)
• branches_lty - set the line type of branches (assign_values_to_branches_edgePar)
• by_labels_branches_col - set the color of branches with specific labels (branches_attr_by_labels)
• by_labels_branches_lwd - set the line width of branches with specific labels (branches_attr_by_labels)
• by_labels_branches_lty - set the line type of branches with specific labels (branches_attr_by_labels)
• by_lists_branches_col - set the color of branches from the root of the tree down to (possibly inner) nodes with specified members (branches_attr_by_lists)
• by_lists_branches_lwd - set the line width of branches from the root of the tree down to (possibly inner) nodes with specified members (branches_attr_by_lists)
• by_lists_branches_lty - set the line type of branches from the root of the tree down to (possibly inner) nodes with specified members (branches_attr_by_lists)
• highlight_branches_col - highlight branches color based on branches’ heights (highlight_branches_col)
• highlight_branches_lwd - highlight branches line-width based on branches’ heights (highlight_branches_lwd)
• clear_branches - clear branches’ attributes (remove_branches_edgePar)
• clear_leaves - clear leaves’ attributes (remove_branches_edgePar)

Value

An updated dendrogram (or dendlist), with some change to the parameters of it

See Also

set("by_lists_branches_lty", L, TF_value = 3) %>%
plot
# A few dendlist examples:
dendlist(dend,dend) %>% set("hang") %>% plot

dendlist(dend,dend) %>% set("branches_k_col", k=3) %>% plot

dendlist(dend,dend) %>% set("labels_col", c(1,2)) %>% plot

dendlist(dend,dend) %>%
  set("hang") %>%
  set("labels_col", c(1,2), which = 1) %>%
  set("branches_k_col", k=3, which = 2) %>%
  set("labels_cex", 1.2) %>%
  plot

# example of modifying the dendrogram in a heatmap:

library(gplots)
data(mtcars)
x <- as.matrix(mtcars)
rc <- rainbow(nrow(x), start=0, end=.3)
cc <- rainbow(ncol(x), start=0, end=.3)

##' demonstrate the effect of row and column dendrogram options
##
Rowv_dend <- x %>% dist %>% hclust %>%
  as.dendrogram %>%
  set("branches_k", k = 3) %>%
  set("branches_lwd", 2) %>% ladderize # rotate_DendSer

Colv_dend <- t(x) %>% dist %>% hclust %>%
  as.dendrogram %>%
  set("branches_k", k = 3) %>%
  set("branches_lwd", 2) %>% ladderize # rotate_DendSer

heatmap.2(x, Rowv = Rowv_dend, Colv = Colv_dend)

## End(Not run)
Description

Convenience functions for updating the labels of a dendrogram. set_labels and place_labels differs in their assumption about the order of the labels. * set_labels assumes the labels are in the same order as that of the labels in the dendrogram. * place_labels assumes the labels has the same order as that of the items in the original data matrix. This is useful for renaming labels based on some other columns in the data matrix.

Usage

```r
set_labels(dend, labels, ...) 
```

Arguments

- `dend` : a `dendrogram` object
- `labels` : A vector of values to insert in the labels of a dendrogram.
- `...` : Currently ignored.

Value

The updated `dendrogram` object

Author(s)

Tal Galili, Garrett Grolemund

See Also

Examples

```r
ss <- c(50, 114, 17, 102, 76, 10, 107, 84, 31, 37, 49, 106, 44, 119, 104, 145, 67, 85, 12, 77, 22, 136, 38, 135, 70)

small_iris <- iris[ss, ]

small_iris[, -5] %>%
  dist() %>%
  hclust(method = "complete") %>%
  as.dendrogram() %>%
  color_branches(k = 3) %>%
  color_labels(k = 3) %>%
  plot()

# example for using place_labels
small_iris[, -5] %>%
  dist() %>%
  hclust(method = "complete") %>%
  as.dendrogram() %>%
```
shuffle

```
color_branches(k = 3) %>%
color_labels(k = 3) %>%
place_labels(paste(small_iris$Species, 1:25, sep = " ")) %>%
plot()

# example for using set_labels
small_iris[, -5] %>%
dist() %>%
hclust(method = "complete") %>%
as.dendrogram() %>%
color_branches(k = 3) %>%
color_labels(k = 3) %>%
set_labels(1:25) %>%
plot()
```

---

**shuffle**  
*Random rotation of trees*

**Description**

'shuffle' randomly rotates ("shuffles") a tree, changing its presentation while preserving its topology. 'shuffle' is based on `rotate` and through its methods can work for any of the major tree objects in R (`dendrogram/hclust/phylo`).

This function is useful in combination with tanglegram and entanglement.

**Usage**

```
shuffle(dend, ...)

## Default S3 method:
shuffle(dend, ...)

## S3 method for class 'dendrogram'
shuffle(dend, ...)

## S3 method for class 'dendlist'
shuffle(dend, which, ...)

## S3 method for class 'hclust'
shuffle(dend, ...)

## S3 method for class 'phylo'
shuffle(dend, ...)
```
sort_2_clusters_vectors

Description

Sorts two clusters vector by their names and returns a list with the sorted vectors.

Usage

sort_2_clusters_vectors(A1_clusters, A2_clusters,
    assume_sorted_vectors = FALSE, warn = dendextend_options("warn"), ...)
Arguments

- **A1_clusters**
a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A1. These are often obtained by using some k cut on a dendrogram.

- **A2_clusters**
a numeric vector of cluster grouping (numeric) of items, with a name attribute of item name for each element from group A2. These are often obtained by using some k cut on a dendrogram.

- **assume_sorted_vectors**
  logical (FALSE). Can we assume to two group vectors are sorter so that they have the same order of items? IF FALSE (default), then the vectors will be sorted based on their name attribute.

- **warn**
  logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE.

... Ignored.

Value

A list with two elements, corresponding to the two clustering vectors.

See Also

FM_index_profdpmp

Examples

```r
## Not run:

set.seed(23235)
sample(1:150, 4)

hc1 <- hclust(dist(iris[ss, -5]), "com")
hc2 <- hclust(dist(iris[ss, -5]), "single")

# dend1 <- as.dendrogram(hc1)
# dend2 <- as.dendrogram(hc2)

A1_clusters <- cutree(hc1, k=3)
A2_clusters <- sample(cutree(hc1, k=3))

sort_2_clusters_vectors(A1_clusters, A2_clusters, assume_sorted_vectors = TRUE) # no sorting
sort_2_clusters_vectors(A1_clusters, A2_clusters, assume_sorted_vectors = FALSE) # Sorted

## End(Not run)
```
### sort_dist_mat

*Sorts a distance matrix by rows and columns names*

**Description**

Sorts a distance matrix by the names of the rows and columns.

**Usage**

```r
sort_dist_mat(dist_mat, by_rows = TRUE, by_cols = TRUE, ...
```

**Arguments**

- `dist_mat`: a distance matrix.
- `by_rows`: logical (TRUE). Sort the distance matrix by rows?
- `by_cols`: logical (TRUE). Sort the distance matrix by columns?
- `...`: Ignored.

**Value**

A distance matrix (after sorting)

**See Also**

- `dist`
- `cor_cophenetic`

### sort_levels_values

*Sort the values level in a vector*

**Description**

Takes a numeric vector and sort its values so that they would be increasing from left to right. It is different from `sort` in that the function will only "sort" the values levels, and not the vector itself.

This function is useful for `cutree` - making the `sort_cluster_numbers` parameter possible. Using that parameter with `TRUE` makes the clusters id’s from `cutree` to be ordered from left to right. e.g: the left most cluster in the tree will be numbered "1", the one after it will be "2" etc...).

**Usage**

```r
sort_levels_values(x, MARGIN = 2, decreasing = FALSE,
                 force_integer = FALSE, warn = dendextend_options("warn"), ...)
```
Arguments

- **x**: a numeric vector.
- **MARGIN**: passed to apply. It is a vector giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns. Where X has named dimnames, it can be a character vector selecting dimension names.
- **decreasing**: logical (FALSE). Should the sort be increasing or decreasing?
- **force_integer**: logical (FALSE). Should the values returned be integers?
- **warn**: logical (default from dendextend_options("warn") is FALSE). Set if warning are to be issued, it is safer to keep this at TRUE, but for keeping the noise down, the default is FALSE. (for example when x had NA values in it)
- **...**: ignored.

Value

if x is an object - it returns logical - is the object of class dendrogram.

See Also

- `sort`, `fac2num`, `cutree`

Examples

```r
x <- 1:4
sort_levels_values(x) # 1 2 3 4

x <- c(4:1)
names(x) <- letters[x]
attr(x, "keep_me") <- "a cat"
sort_levels_values(x) # 1 2 3 4

x <- c(4:1, 4, 2)
sort_levels_values(x) # 1 2 3 4 1 3

x <- c(2,2,3,2,1)
sort_levels_values(x) # 1 1 2 1 3

x<- matrix(16:1, 4, 4)
rownames(x) <- letters[1:4]
x
apply(x, 2, sort_levels_values)
```
tanglegram  Tanglegram plot

Description

Plots a tanglegram plot of a side by side trees.

Usage

tanglegram(dend1, ...)

## Default S3 method:
tanglegram(dend1, ...)

## S3 method for class 'hclust'
tanglegram(dend1, ...)

## S3 method for class 'phylo'
tanglegram(dend1, ...)

## S3 method for class 'dendlist'
tanglegram(dend1, which = c(1L, 2L), main_left, main_right,
  just_one = TRUE, ...)

## S3 method for class 'dendrogram'
tanglegram(dend1, dend2, sort = FALSE, color_lines,
  lwd = 3.5, edge.lwd = NULL, columns_width = c(5, 3, 5),
  margin_top = 3, margin_bottom = 2.5, margin_inner = 3,
  margin_outer = 0.5, left_dendo_mar = c(margin_bottom, margin_outer,
  margin_top, margin_inner), right_dendo_mar = c(margin_bottom, margin_inner,
  margin_top, margin_outer), intersecting = TRUE, dLeaf = NULL,
  dLeaf_left = dLeaf, dLeaf_right = dLeaf, axes = TRUE, type = "r",
  lab.cex = NULL, remove_nodePar = FALSE, main = "", main_left = "",
  main_right = "", sub = "", k_labels = NULL, k_branches = NULL,
  rank_branches = FALSE, hang = FALSE, match_order_by_labels = TRUE,

  right_dendo_mar = c(margin_bottom, margin_inner, margin_top, margin_outer),
  intersecting = TRUE, dLeaf = NULL, dLeaf_left = dLeaf,
dleaf_right = dleaf, axes = TRUE, type = "r", lab.cex = NULL,
remove_nodePar = FALSE, main = "", main_left = "", main_right = "",
sub = "", k_labels = NULL, k_branches = NULL, rank_branches = FALSE,
hang = FALSE, match_order_by_labels = TRUE, cex_main = 2,
cex_main_left = cex_main, cex_main_right = cex_main, cx_sub = cex_main,
highlight_distinct_edges = TRUE, common_subtrees_color_lines = TRUE,
common_subtrees_color_branches = FALSE, highlight_branches_col = FALSE,
highlight_branches_lwd = TRUE, faster = FALSE, just_one = TRUE, ...)

Arguments

dend1  tree object (dendrogram/dendlist/hclust/phylo), plotted on the left

which  an integer vector of length 2, indicating which of the trees in the dendlist object
should be plotted

main_left  Character. Title of the left dendrogram.

main_right  Character. Title of the right dendrogram.

just_one  logical (TRUE). If FALSE, it means at least two tanglegrams will be plotted on
the same page and so layout is not passed. See: http://stackoverflow.com/q/39784746/4137985

dend2  tree object (dendrogram/hclust/phylo), plotted on the right

sort  logical (FALSE). Should the dendrogram’s labels be “sorted”? (might give a
better tree in some cases).

color_lines  a vector of colors for the lines connected the labels. If the colors are shorter than
the number of labels, they are recycled (and a warning is issued). The colors in
the vector are applied on the lines from the bottom up.

lwd  width of the lines connecting the labels. (default is 3.5)

edge_lwd  width of the dendrograms lines. Default is NULL. If set, then it switches ‘highlight_branches_lwd’ to FALSE. If you want thicker lines which reflect the height,
please use highlight_branches_lwd on the dendrograms/dendlist.

columns_width  a vector with three elements, giving the relative sizes of the the three plots (left
dendrogram, connecting lines, right dendrogram). This is passed to layout if
parameter just_one is TRUE. The default is: c(5,3,5)

margin_top  the number of lines of margin to be specified on the top of the plots.

margin_bottom  the number of lines of margin to be specified on the bottom of the plots.

margin_inner  margin_bottom the number of lines of margin to be specified on the inner dis-
tance between the dendrograms and the connecting lines.

margin_outer  margin_bottom the number of lines of margin to be specified on the outer dis-
tance between the dendrograms and the connecting lines.

left_dendo_mar  mar parameters of the left dendrogram.

right_dendo_mar  mar parameters of the right dendrogram.

intersecting  logical (TRUE). Should the leaves of the two dendrograms be pruned so that the
two trees will have the same labels?
dLeaf  a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL, as per default, 3/4 of a letter width or height is used.
Notice that if we are comparing two dendrograms with different heights, manually changing dLeaf will affect both trees differently. In such a case, it is recommended to manually change dLeaf_left and dLeaf_right. This can be especially important when changing the lab.cex of the dendrogram’s labels. Alternatively, one could manually set the xlim parameter for both trees, which will force the proportion of distances of the labels from the trees to remain the same.

dLeaf_left  dLeaf of the left dendrogram, by default it is equal to dLeaf (often negative).
dLeaf_right  dLeaf of the right dendrogram, by default it is equal to minus dLeaf (often positive).
axes  logical (TRUE). Should plot axes be plotted?
type  type of plot ("t"/"r" = triangle or rectangle)
lab.cex  numeric scalar, influencing the cex size of the labels.
remove_nodePar  logical (FALSE). Should the nodePar of the leaves be removed? (useful when the trees’ leaves has too many parameters on them)
main  Character. Title above the connecting lines.
sub  Character. Title below the connecting lines.
k_labels  integer. Number of groups by which to color the leaves.
k_branches  integer. Number of groups by which to color the branches.
rank_branches  logical (FALSE). Should the branches heights be adjusted? (setting this to TRUE - can make it easier for comparing topological differences)
hang  logical (FALSE). Should we hang the leaves of the trees?
match_order_by_labels  logical (TRUE). Should the leaves value order be matched between the two trees based on labels? This is a MUST in order to have the lines connect the correct labels. Set this to FALSE if you want to make the plotting a bit faster, and only after you are sure the labels and orders are correctly aligned.
cex_main  A numerical value giving the amount by which plotting title should be magnified relative to the default.
cex_main_left  see cex_main.
cex_main_right  see cex_main.
cex_sub  see cex_main.
highlight_distinct_edges  logical (default is TRUE). If to highlight distinct edges in each tree (by changing their line types to 2). (notice that this can be slow on large trees)
This parameter will automatically be turned off if the tree already comes with a "lty" edgePar (this is checked using has_edgePar). A "lty" can be removed by using set("clear_branches"), by removing all of the edgePar parameters of the dendrogram.
common_subtrees_color_lines  logical (default is TRUE). color the connecting line based on the common sub-trees of both dends. This only works if (notice that this can be slow on large trees)
common_subtrees_color_branches
logical (default is FALSE). Color the branches of both dends based on the common subtrees. (notice that this can be slow on large trees) This is FALSE by default since it will override the colors of the existing tree.

highlight_branches_col
logical (default is FALSE). Should highlight_branches_col be used on the dendrograms.
This parameter will automatically be turned off if the tree already comes with a "col" edgePar (this is checked using has_edgePar). A "lty" can be removed by using set("clear_branches"), by removing all of the edgePar parameters of the dendrogram.

highlight_branches_lwd
logical (default is TRUE). Should highlight_branches_lwd be used on the dendrograms.
This parameter will automatically be turned off if the tree already comes with a "lwd" edgePar (this is checked using has_edgePar). A "lty" can be removed by using set("clear_branches"), by removing all of the edgePar parameters of the dendrogram.

faster
logical (FALSE). If TRUE, it overrides some other parameters to have them turned off so that the plotting will go a tiny bit faster.

Details
Notice that tanglegram does not "resize" well. In case you are resizing your window you would need to re-run the function.

Value
An invisible dendlist, with two trees after being modified during the creation of the tanglegram.

Author(s)
Tal Galili, Johan Renaudie

Source
The function is based on code from Johan Renaudie (plannapus), after major revisions. See: http://stackoverflow.com/questions/12456768/duelling-dendrograms-in-r-placing-dendrograms-back-to-back-
As far as I could tell, this code was originally inspired by Dylan Beaudette function dueling.dendrograms from the sharpshootR package: http://cran.at.r-project.org/web/packages/sharpshootR/

---

**theme_dendro**

*Creates completely blank theme in ggplot*

---

**Description**

Sets most of the ggplot options to blank, by returning blank theme elements for the panel grid, panel background, axis title, axis text, axis line and axis ticks.

**Usage**

```r
theme_dendro()
```

**Author(s)**

Andrie de Vries

**Source**

This function is from Andrie de Vries’s ggdendro package.

The motivation for this fork is the need to add more graphical parameters to the plotted tree. This required a strong mixter of functions from ggdendro and dendextend (to the point that it seemed better to just fork the code into its current form)

**See Also**

`ggdend`

---

**unbranch**

*unbranch trees*

---

**Description**

unbranch trees and merges the subtree to the parent node.
Usage

unbranch(dend, ...)

## Default S3 method:
unbranch(dend, ...)

## S3 method for class 'dendrogram'
unbranch(dend, branch_becoming_root = 1, new_root_height, ...)

## S3 method for class 'hclust'
unbranch(dend, branch_becoming_root = 1, new_root_height, ...)

## S3 method for class 'phylo'
unbranch(dend, ...)

Arguments

dend a dendrogram (or hclust) object
... passed on
branch_becoming_root a numeric choosing the branch of the root which will become the new root (from left to right)
new_root_height the new height of the branch which will become the new root. If the parameter is not given - the height of the original root is used.

Value
An unbranched dendrogram

See Also
unroot ape

Examples

hc <- hclust(dist(USArrests[2:9,]), "com")
dend <- as.dendrogram(hc)

par(mfrow = c(1,3))
plot(dend, main = "original tree")
plot(unbranch(dend, 1), main = "unbranched tree (left branch")
plot(unbranch(dend, 2), main = "tree without (right branch")
unclass_dend

unclass_dend (unclass an entire dendrogram tree)

Description

unclass all the nodes in a dendrogram tree. (Helps in cases when a dendrapply function was used wrongly)

Usage

unclass_dend(dend, ...)

Arguments

dend a dendrogram object

... not used

Value

The list which was the dendrogram (but without a class)

See Also

nleaves

Examples

# define dendrogram object to play with:
hc <- hclust(dist(USArrests[,3:1]), "ave")
dend <- as.dendrogram(hc)

itself <- function(x) x
dend <- dendrapply(dend, itself)
unclass(dend) # this only returns a list with
  # two dendrogram objects inside it.
str(dend) # this is a great way to show a dendrogram,
  # but it doesn't help us understand how the R object is built.
str(unclass(dend)) # this is a great way to show a dendrogram,
  # but it doesn't help us understand how the R object is built.
unclass_dend(dend) # this only returns a list
  # with two dendrogram objects inside it.
str(unclass_dend(dend)) # NOW we can more easily understand
  # how the dendrogram object is structured...
Description

One untangle function to rule them all.

This function untangles dendrogram lists (dendlist), using various heuristics.

Usage

untangle(dend1, ...)

## Default S3 method:
untangle(dend1, ...)

untangle_labels(dend1, dend2, ...)

## S3 method for class 'dendrogram'
untangle(dend1, dend2, method = c("labels", "ladderize", "random", "step1side", "step2side", "DendSer"), ...)

## S3 method for class 'dendlist'
untangle(dend1, method = c("labels", "ladderize", "random", "step1side", "step2side", "DendSer"), which = c(1L, 2L), ...)

Arguments

dend1 a dendrogram or a dendlist object
... passed to the relevant untangle function
dend2 A second dendrogram (to untangle against)
method a character indicating the type of untangle heuristic to use.
which an integer vector of length 2, indicating which of the trees in the dendlist object should be plotted

Details

This function wraps all of the untangle functions, in order to make it easier to find out about (and use) them.

Value

A dendlist, with two trees after they have been untangled.

If the dendlist was originally larger than 2, it will return the original dendlist but with the relevant trees properly rotate.
untangle_DendSer

Author(s)

Tal Galili

tanglegram, untangle_random_search, untangle_step_rotate_1side, untangle_step_rotate_2side, untangle_DendSer, entanglement

Examples

```r
## Not run:
set.seed(23235)
ss <- sample(1:150, 10)
dend1 <- iris[ss,5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[ss,5] %>% dist %>% hclust("sin") %>% as.dendrogram
dend12 <- dendlist(dend1, dend2)

dend12 %>% tanglegram

untangle(dend1, dend2, method="random", R = 5) %>% tanglegram

# it works, and we get something different:
set.seed(1234)
dend12 %>% untangle(method="random", R = 5) %>% tanglegram

set.seed(1234)
# fixes it completely:
dend12 %>% untangle(method="random", R = 5) %>% untangle(method="step1") %>% tanglegram
# not good enough
dend12 %>% untangle(method="step1") %>% tanglegram
# not good enough
dend12 %>% untangle(method="step2") %>% tanglegram
# How we might wish to use it:
set.seed(12777)
dend12 %>%
  untangle(method="random", R = 1) %>%
  untangle(method="step2") %>%
tanglegram
```

## End(Not run)

untangle_DendSer  

Tries to run DendSer on a dendrogram

Description

The function tries to turn the dend into hclust. It then uses the cophenetic distance matrix for optimizing the tree’s rotation.

This is a good (and fast) starting point for linkuntangle_step_rotate_2side
Usage

```r
untangle_random_search(dend1, dend2, R = 100L, L = 1,
leaves_matching_method = c("labels", "order"), ...)
```

Description

Searches for two untangled dendrograms by randomly shuffling them and each time checking if their entanglement was improved.
Arguments

dend1 a tree object (of class dendrogram/hclust/phylo).
dend2 a tree object (of class dendrogram/hclust/phylo).
R numeric (default is 100). The number of shuffles to perform.
L the distance norm to use for measuring the distance between the two trees. It can be any positive number, often one will want to use 0, 1, 1.5, 2 (see 'details' for more). It is passed to entanglement.
leaves_matching_method a character scalar passed to entanglement. It can be either "order" or "labels" (default). If using "labels", then we use the labels for matching the leaves order value. And if "order" then we use the old leaves order value for matching the leaves order value.

Details

Untangling two trees is a hard combinatorical problem without a closed form solution. One way for doing it is to run through a random spectrum of options and look for the "best" two trees. This is what this function offers.

Value

A dendlist with two trees with the best entanglement that was found.

See Also

tanglegram, match_order_by_labels, entanglement.

Examples

```R
## Not run:
dend1 <- iris[,5] %>% dist %>% hclust("com") %>% as.dendrogram
dend2 <- iris[,5] %>% dist %>% hclust("sin") %>% as.dendrogram
tanglegram(dend1, dend2)
set.seed(65168)
dend12 <- untangle_random_search(dend1, dend2, R = 10)
tanglegram(dend12[[1]], dend12[[2]])
tanglegram(dend12)
```
untangle_step_rotate_1side

Stepwise untangle one tree compared to another

Description

Given a fixed tree and a tree we wish to rotate, this function goes through all of the k number of clusters (from 2 onward), and each time rotates the branch which was introduced in the new k’th cluster. This rotated tree is compared with the fixed tree, and if it has a better entanglement, it will be used for the following iterations.

This is a greedy forward selection algorithm for rotating the tree and looking for a better match.

This is useful for finding good trees for a tanglegram.

Usage

untangle_step_rotate_1side(dend1, dend2_fixed, L = 2, direction = c("forward", "backward"), k_seq = NULL, dend_heights_per_k, leaves_matching_method = c("labels", "order"), ...)

Arguments

dend1
a dendrogram object. The one we will rotate to best fit dend2_fixed.

dend2_fixed
a dendrogram object. This one is kept fixed.

L
the distance norm to use for measuring the distance between the two trees. It can be any positive number, often one will want to use 0, 1, 1.5, 2 (see 'details' in entanglement).

direction
a character scalar, either "forward" (default) or "backward". Impacts the direction of clustering that are tried. Either from 2 and up (in case of "forward"), or from nleaves to down (in case of "backward")

If k_seq is not NULL, then it overrides "direction".

k_seq
a sequence of k clusters to go through for improving dend1. If NULL (default), then we use the "direction" parameter.

dend_heights_per_k
a numeric vector of values which indicate which height will produce which number of clusters (k)
**untangle_step_rotate_2side**

leaves_matching_method

a character scalar passed to entanglement. It can be either "order" or "labels" (default). If using "labels", then we use the labels for matching the leaves order value. And if "order" then we use the old leaves order value for matching the leaves order value.

Using "order" is faster, but "labels" is safer. "order" will assume that the original two trees had their labels and order values MATCHED.

Hence, it is best to make sure that the trees used here have the same labels and the SAME values matched to these values - and then use "order" (for fastest results).

If "order" is used, the function first calls match_order_by_labels in order to make sure that the two trees have their labels synced with their leaves order values.

... not used

**Value**

A dendlist with 1) dend1 after it was rotated to best fit dend2_fixed. 2) dend2_fixed.

**See Also**

untangle, match_order_by_labels, entanglement, flip_leaves, all_couple_rotations_at_k, untangle_step_rotate_2side.

**Examples**

```r
# Not run:
dend1 <- USArrests[1:10,] %>% dist %>% hclust %>% as.dendrogram
set.seed(3525)
dend2 <- shuffle(dend1)
tanglegram(dend1, dend2)
entanglement(dend1, dend2, L = 2) # 0.4727

dend2_corrected <- untangle_step_rotate_1side(dend2, dend1)[[1]]
tanglegram(dend1, dend2_corrected) # FIXED.
entanglement(dend1, dend2_corrected, L = 2) # 0

# End(Not run)
```

---

**untangle_step_rotate_2side**

*Stepwise untangle two trees one at a time*
Description

This is a greedy forward selection algorithm for rotating the tree and looking for a better match.
This is useful for finding good trees for a tanglegram.

It goes through rotating dend1, then dend2, and so on - until a locally optimal solution is found.
Similar to "step1side", one tree is held fixed and the other tree is rotated. This function goes through all of the k number of clusters (from 2 onward), and each time rotates the branch which was introduced in the new k'th cluster. This rotated tree is compared with the fixed tree, and if it has a better entanglement, it will be used for the following iterations. Once finished the rotated tree is held fixed, and the fixed tree is now rotated. This continues until a local optimal solution is reached.

Usage

untangle_step_rotate_2side(dend1, dend2, L = 1.5, direction = c("forward", "backward"), max_n_iterations = 10L, print_times = dendextend_options("warn"), k_seq = NULL, ...)

Arguments

dend1        a dendrogram object. The one we will rotate to best fit dend2.
dend2        a dendrogram object. The one we will rotate to best fit dend1.
L            the distance norm to use for measuring the distance between the two trees. It can be any positive number, often one will want to use 0, 1, 1.5, 2 (see 'details' in entanglement).
direction    a character scalar, either "forward" (default) or "backward". Impacts the direction of clustering that are tried. Either from 2 and up (in case of "forward"), or from nleaves to down (in case of "backward")
If k_seq is not NULL, then it overrides "direction".
max_n_iterations integer. The maximal number of times to switch between optimizing one tree with another.
print_times   logical (TRUE), should we print how many times we switched between rotating the two trees?
k_seq        a sequence of k clusters to go through for improving dend1. If NULL (default), then we use the "direction" parameter.
...           not used

Value

A list with two dendrograms (dend1/dend2), after they are rotated to best fit one another.

which_leaf

Examples

```r
## Not run:
dend1 <- USArrests[1:20,] %>% dist %>% hclust %>% as.dendrogram
dend2 <- USArrests[1:20,] %>% dist %>% hclust(method = "single") %>% as.dendrogram
set.seed(3525)
dend2 <- shuffle(dend2)
tanglegram(dend1,dend2, margin_inner=6.5)
entanglement(dend1,dend2, L = 2) # 0.79

dend2_corrected <- untangle_step_rotate_1side(dend2, dend1)
tanglegram(dend1,dend2_corrected, margin_inner=6.5) # Good.
entanglement(dend1,dend2_corrected, L = 2) # 0.0067
# it is better, but not perfect. Can we improve it?
dend12_corrected <- untangle_step_rotate_2side(dend1, dend2)
tanglegram(dend12_corrected[[1]],dend12_corrected[[2]], margin_inner=6.5) # Better...
entanglement(dend12_corrected[[1]],dend12_corrected[[2]], L=2) # 0.0045

# best combination:
dend12_corrected_1 <- untangle_random_search(dend1, dend2)
dend12_corrected_2 <- untangle_step_rotate_2side(dend12_corrected_1[[1]],dend12_corrected_1[[2]])
tanglegram(dend12_corrected_2[[1]],dend12_corrected_2[[2]], margin_inner=6.5) # Better...
entanglement(dend12_corrected_2[[1]],dend12_corrected_2[[2]], L=2) # 0 - PERFECT.
## End(Not run)
```

which_leaf

Which node is a leaf?

Description

Gives a vector as the number of nodes (nnodes), which gives a TRUE when a node is a leaf.

Usage

```r
which_leaf(dend, ...)
```

Arguments

- `dend`: a dendrogram
- `...`: ignored.

Value

A logical vector with the length of `nnodes`, which gives a TRUE when a node is a leaf.
which_node

Which node id is common to a group of labels

Description
This function identifies which edge(s) in a tree has group of labels ("tips") in common. By default it only returns the edge (node) with the heighest id.

Usage
which_node(dend, labels, max_id = TRUE, ...)

Arguments
dend a dendrogram dend
labels a character vector of labels from the tree
max_id logical (TRUE) - if to return only the max id
... ignored.

Value
An integer with the id(s) of the nodes which includes all of the labels.

See Also
