Package ‘geoR’

May 2, 2016

Version 1.7-5.2
Date 2016-05-02
Title Analysis of Geostatistical Data
LazyLoad yes
LazyData yes
Author Paulo J. Ribeiro Jr <paulojus@ufpr.br> and
Peter J. Diggle <p.diggle@lancaster.ac.uk>
Maintainer Paulo J. Ribeiro Jr <paulojus@ufpr.br>
Depends R (>= 2.10), stats, methods
Imports MASS, sp, splancs, RandomFields, graphics
Suggests scatterplot3d, lattice, tcltk, geoRglm
Description Geostatistical analysis including traditional, likelihood-based and Bayesian methods.
License GPL (>= 2)
URL http://www.leg.ufpr.br/geoR
NeedsCompilation yes
Repository CRAN
Date/Publication 2016-05-02 14:27:02

Adapts nlm for Constraints in the Parameter Values

Description

This function adapts the R function nlm to allow for constraints (upper and/or lower bounds) in the values of the parameters.
Usage

```r
.nlmP(objfunc, params, lower=rep(-Inf, length(params)),
       upper=rep(+Inf, length(params)), ...)
```

Arguments

- `objfunc`: the function to be minimized.
- `params`: starting values for the parameters.
- `lower`: lower bounds for the variables. Defaults to $-Inf$.
- `upper`: upper bounds for the variables. Defaults to $-Inf$.
- `...`: further arguments to be passed to the function `nlm`.

Details

Constraints on the parameter values are internally imposed by using exponential, logarithmic, and logit transformation of the parameter values.

Value

The output is the same as for the function `nlm`.

Author(s)

Patrick E. Brown <p.brown@lancaster.ac.uk>.
Adapted and included in `geoR` by
Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>

---

**as.geodata**

*Converts an Object to the Class "geodata"*

**Description**

The default method converts a matrix or a data-frame to an object of the class "geodata".
Objects of the class "geodata" are lists with two obligatory components: coords and data. Optional components are allowed and a typical example is a vector or matrix with covariate(s) values.
as.geodata

Usage

as.geodata(obj, ...)

## Default S3 method:
as.geodata(obj, coords.col = 1:2, data.col = 3, data.names = NULL,
covar.col = NULL, covar.names = "obj.names",
units.m.col = NULL, realisations = NULL,
na.action = c("ifany", "ifdata", "ifcovar", "none"),
rep.data.action, rep.covar.action, rep.units.action,
...)

## S3 method for class 'geodata'
as.data.frame(x, ..., borders = TRUE)

## S3 method for class 'geodata.frame'
as.geodata(obj, ...)

## S3 method for class 'SpatialPointsDataFrame'
as.geodata(obj, data.col = 1, ...)

is.geodata(x)

Arguments

obj a matrix or data-frame where each line corresponds to one spatial location. It should contain values of 2D coordinates, data and, optionally, covariate(s) value(s) at the locations. A method for SpatialPointsDataFrame is also provided. It can also take an output of the function grf, see DETAILS below.

c知名.col a vector with the column numbers corresponding to the spatial coordinates.
data.col a scalar or vector with column number(s) corresponding to the data.
data.names optional. A string or vector of strings with names for the data columns. Only valid if there is more than one column of data. By default, takes the names from the original object.
covar.col optional. A scalar or numeric vector with the column number(s) corresponding to the covariate(s). Alternativelly can be a character vector with the names of the covariates.
covar.names optional. A string or vector of strings with the name(s) of the covariates. By default take the names from the original object.
units.m.col optional. A scalar with the column number corresponding to the offset variable. Alternativelly can be a character vector with the name of the offset. This option is particularly relevant when using the package geoRglm. All values must be greater then zero.
realisations optional. A vector indicating the realisation number or a number indicating a column in obj with the realisation indicator variable. See DETAILS below.
na.action string defining action to be taken in the presence of NA's. The default option "ifany" excludes all points for which there are NA's in the data or covariates.
The option "ifdata" excludes points for which there are NA's in the data. The default option "ifcovar" excludes all points for which there are NA's in the covariates. The option "none" do not exclude points.

**rep.data.action**

A string or a function. Defines action to be taken when there is more than one data at the same location. The default option "none" keeps the repeated locations, if any. The option "first" retains only the first data recorded at each location. Alternatively a function can be passed and it will be used. For instance if \texttt{mean} is provided, the function will compute and return the average of the data at coincident locations. The non-default options will eliminate the repeated locations.

**rep.covar.action**

Idem to \texttt{rep.data.locations}, to be applied to the covariates, if any. Defaults to the same option set for \texttt{rep.data.locations}.

**x**

An object which is tested for the class \texttt{geodata}.

**rep.units.action**

A string or a function. Defines action to be taken on the element \texttt{units.m}, if present when there is more than one data at the same location. The default option is the same value set for \texttt{rep.data.action}.

**borders**

Logical. If TRUE the element borders in the geodata object is set as an attribute of the data-frame.

... values to be passed for the methods.

**Details**

Objects of the class "geodata" contain data for geostatistical analysis using the package \texttt{geoR}. Storing data in this format facilitates the usage of the functions in \texttt{geoR}. However, conversion of objects to this class is not obligatory to carry out the analysis.

NA's are not allowed in the coordinates. By default the respective rows will not be included in the output.

**Realisations**

Typically geostatistical data correspond to a unique realisation of the spatial process. However, sometimes different "realisations" are possible. For instance, if data are collected in the same area at different points in time and independence between time points is assumed, each time can be considered a different "replicate" or "realisation" of the same process. The argument \texttt{realisations} takes a vector indication the replication number and can be passed to other \texttt{geoR} functions as, for instance, \texttt{likfit}.

The data format is similar to the usual geodata format in \texttt{geoR}. Suppose there are realisations (times) 1, \ldots, J and for each realisations \(n_1, \ldots, n_j\) observations are available. The coordinates for different realisations should be combined in a single \(n \times 2\) object, where \(n = n_1 + \ldots + n_J\). Similarly for the data vector and covariates (if any).

**grf objects**

If an object of the class \texttt{grf} is provided the functions just extracts the elements \texttt{coords} and \texttt{data} of this object.
Box-Cox Transformed Normal Distribution

Value

An object of the class "geodata" which is a list with two obligatory components (coords and data) and other optional components:

coords an \( n \times 2 \) matrix where \( n \) is the number of spatial locations.
data a vector of length \( n \), for the univariate case or, an \( n \times v \) matrix or data-frame for the multivariate case, where \( v \) is the number of variables.
covariates a vector of length \( n \) or an \( n \times p \) matrix with covariate(s) values, where \( p \) is the number of covariates. Only returned if covariates are provided.
realisations a vector on size \( n \) with the replication number. Only returned if argument realisations is provided.

Examples

```r
## Not run:
## converting the data-set "topo" from the package MASS (VR's bundle)
## to the geodata format:
if(require(MASS)){
topo
topogeo <- as.geodata(topo)
names(topogeo)
topogeo
}
## End(Not run)
```

The Box-Cox Transformed Normal Distribution

Description

Functions related with the Box-Cox family of transformations. Density and random generation for the Box-Cox transformed normal distribution with mean equal to \( \text{mean} \) and standard deviation equal to \( \text{sd} \), in the normal scale.
Usage

rboxcox(n, lambda, lambda2 = NULL, mean = 0, sd = 1)
dboxcox(x, lambda, lambda2 = NULL, mean = 0, sd = 1)

Arguments

lambda  numerical value(s) for the transformation parameter $\lambda$.
lambda2  logical or numerical value(s) of the additional transformation (see DETAILS below). Defaults to NULL.
n  number of observations to be generated.
x  a vector of quantiles (dboxcox) or an output of boxcoxfit (print, plot, lines).
mean  a vector of mean values at the normal scale.
sd  a vector of standard deviations at the normal scale.

Details

Denote $Y$ the variable at the original scale and $Y'$ the transformed variable. The Box-Cox transformation is defined by:

$$Y' = \begin{cases} 
\log(Y) , & \text{if } \lambda = 0 \\
\frac{Y^{\lambda} - 1}{\lambda} , & \text{otherwise}
\end{cases}$$

An additional shifting parameter $\lambda_2$ can be included in which case the transformation is given by:

$$Y' = \begin{cases} 
\log(Y + \lambda_2) , & \lambda = 0 \\
\frac{(Y + \lambda_2)^\lambda - 1}{\lambda} , & \text{otherwise}
\end{cases}$$

The function rboxcox samples $Y'$ from the normal distribution using the function rnorm and back-transform the values according to the equations above to obtain values of $Y$. If necessary the back-transformation truncates the values such that $Y' \geq \frac{1}{\lambda}$ results in $Y = 0$ in the original scale. Increasing the value of the mean and/or reducing the variance might help to avoid truncation.

Value

The functions returns the following results:

rboxcox  a vector of random deviates.
dboxcox  a vector of densities.

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.
References

See Also

The parameter estimation function boxcoxfit, the function boxcox in the package MASS and the function box.co in the package car.

Examples

```r
## Simulating data
simul <- rboxcox(100, lambda=0.5, mean=10, sd=2)
## Comparing models with different lambdas,
## zero means and unit variances
curve(dboxcox(x, lambda=-1), 0, 0)
for(lambda in seq(-5, 1.5, by=0.5))
  curve(dboxcox(x, lambda), 0, 0, add = TRUE)
```

boxcox.geodata  

Box-Cox transformation for geodata objects

Description

Method for Box-Cox transformation for objects of the class geodata assuming the data are independent. Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox simple power transformation $y^{\lambda}$.

Usage

```r
## S3 method for class 'geodata'
boxcox(object, trend = "cte", ...)
```

Arguments

- **object**: an object of the class geodata. See as.geodata.
- **trend**: specifies the mean part of the model. See trend.spatial for further details. Defaults to "cte".
- **...**: arguments to be passed for the function boxcox.

Details

This is just a wrapper for the function boxcox facilitating its usage with geodata objects. Notice this assume independent observations which is typically not the case for geodata objects.
boxcoxfit

Value

A list of the lambda vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

See Also

boxcox for parameter estimation results for independent data and likfit for parameter estimation within the geostatistical model.

Examples

```r
if(require(MASS)){
  boxcox(wolfcamp)
  data(ca20)
  boxcox(ca20, trend = -altitude)
}
```

boxcoxfit  Parameter Estimation for the Box-Cox Transformation

Description

Parameter estimation and plotting of the results for the Box-Cox transformed normal distribution.

Usage

```r
boxcoxfit(object, xmat, lambda, lambda2 = NULL, add.to.data = FALSE, ...)
```

## S3 method for class 'boxcoxfit'
print(x, ...)

## S3 method for class 'boxcoxfit'
plot(x, hist = TRUE, data = eval(x$call$object), ...)

## S3 method for class 'boxcoxfit'
lines(x, data = eval(x$call$object), ...)

Arguments

- **object** a vector with the data.
- **xmat** a matrix with covariates values. Defaults to `rep(1, length(y))`.
- **lambda** numerical value(s) for the transformation parameter \( \lambda \). Used as the initial value in the function for parameter estimation. If not provided default values are assumed. If multiple values are passed the one with highest likelihood is used as initial value.
lambda2  logical or numerical value(s) of the additional transformation (see DETAILS below). Defaults to NULL. If TRUE this parameter is also estimated and the initial value is set to the absolute value of the minimum data. A numerical value is provided it is used as the initial value. Multiple values are allowed as for lambda.

add.to.data a constant value to be added to the data.

x a list, typically an output of the function boxcoxfit.

hist logical indicating whether histograms should be plotted.

data data values.

... extra parameters to be passed to the minimization function optim (boxcoxfit), hist (plot) or curve (lines).

Value

The functions returns the following results:

boxcoxfit a list with estimated parameters and results on the numerical minimization.

print.boxcoxfit print estimated parameters. No values returned.

plot.boxcoxfit plots histogram of the data (optional) and the model. No values returned. This function is only valid if covariates are not included in boxcoxfit.

lines.boxcoxfit adds a line with the fitted model to the current plot. No values returned. This function is only valid if covariates are not included in boxcoxfit.

**ca20**

*Calcium content in soil samples*

**Description**

This data set contains the calcium content measured in soil samples taken from the 0-20cm layer at 178 locations within a certain study area divided in three sub-areas. The elevation at each location was also recorded.

The first region is typically flooded during the rain season and not used as an experimental area. The calcium levels would represent the natural content in the region. The second region has received fertilisers a while ago and is typically occupied by rice fields. The third region has received fertilisers recently and is frequently used as an experimental area.

**Usage**

```r
data(ca20)
```

**Format**

The object `ca20` belongs to the class `geodata` and is a list with the following elements:

- `coords` a matrix with the coordinates of the soil samples.
- `data` calcium content measured in $\text{mmol}_c/\text{dm}^3$.
- `covariate` a data-frame with the covariates
  - `altitude` a vector with the elevation of each sampling location, in meters ($m$).
  - `area` a factor indicating the sub area to which the locations belongs.
- `borders` a matrix with the coordinates defining the borders of the area.
- `reg1` a matrix with the coordinates of the limits of the sub-area 1.
- `reg2` a matrix with the coordinates of the limits of the sub-area 2.
- `reg3` a matrix with the coordinates of the limits of the sub-area 3.
**Source**

The data was collected by researchers from PESAGRO and EMBRAPA-Solos, Rio de Janeiro, Brasil and provided by Dra. Maria Cristina Neves de Oliveira. 

**References**

Further information on the package `geoR` can be found at: [http://www.leg.ufpr.br/geoR](http://www.leg.ufpr.br/geoR).

---

**camg**

*Calcium and magnesium content in soil samples*

**Description**

This data set contains the calcium content measured in soil samples taken from the 0-20cm layer at 178 locations within a certain study area divided in three sub-areas. The elevation at each location was also recorded.

The first region is typically flooded during the rain season and not used as an experimental area. The calcium levels would represent the natural content in the region. The second region has received fertilizers a while ago and is typically occupied by rice fields. The third region has received fertilizers recently and is frequently used as an experimental area.

**Usage**

`data(camg)`

**Format**

A data frame with 178 observations on the following 10 variables.

- **east** east-west coordinates, in meters.
- **north** north-south coordinates, in meters.
- **elevation** elevation, in meters.
- **region** a factor where numbers indicate different sub-regions within the area.
- **ca020** calcium content in the 0-20cm soil layer, measured in mmol/cdm^3^.
- **mg020** calcium content in the 0-20cm soil layer, measured in mmol/cdm^3^.
- **ctc020** calcium content in the 0-20cm soil layer.
ca2040 calcium content in the 20-40cm soil layer, measured in $\text{mmol}_c/dm^3$.

mg2040 calcium content in the 20-40cm soil layer, measured in $\text{mmol}_c/dm^3$.

ctc2040 calcium content in the 20-40cm soil layer.

Details

More details about this data-set, including coordinates of the region and sub-region borders can be found in the data object ca20.

Source

The data was collected by researchers from PESAGRO and EMBRAPA-Solos, Rio de Janeiro, Brasil and provided by Dra. Maria Cristina Neves de Oliveira.

Examples

```r
plot(camg[-1:2,])
mg20 <- as.geodata(camg, data.col=6)
plot(mg20)
points(mg20)
```

coords.aniso  

### Geometric Anisotropy Correction

**Description**

Transforms or back-transforms a set of coordinates according to the geometric anisotropy parameters.

**Usage**

```r
coords.aniso(coords, aniso.pars, reverse = FALSE)
```

**Arguments**

- `coords`: an $n \times 2$ matrix with the coordinates to be transformed.
- `aniso.pars`: a vector with two elements, $\psi_A$ and $\psi_R$, the anisotropy angle and the anisotropy ratio, respectively. Notice that the parameters must be provided in this order. See section DETAILS below for more information on anisotropy parameters.
- `reverse`: logical. Defaults to FALSE. If TRUE the reverse transformation is performed.
Details

Geometric anisotropy is defined by two parameters:

**Anisotropy angle** defined here as the azimuth angle of the direction with greater spatial continuity, i.e. the angle between the y-axis and the direction with the maximum range.

**Anisotropy ratio** defined here as the ratio between the ranges of the directions with greater and smaller continuity, i.e. the ratio between maximum and minimum ranges. Therefore, its value is always greater or equal to one.

If `reverse = FALSE` (the default) the coordinates are transformed from the *anisotropic space* to the *isotropic space*. The transformation consists in multiplying the original coordinates by a rotation matrix $R$ and a shrinking matrix $T$, as follows:

$$X_m = XRT,$$

where $X_m$ is a matrix with the modified coordinates (isotropic space), $X$ is a matrix with original coordinates (anisotropic space), $R$ rotates coordinates according to the anisotropy angle $\psi_A$ and $T$ shrinks the coordinates according to the anisotropy ratio $\psi_R$.

If `reverse = TRUE`, the back-transformation is performed, i.e. transforming the coordinates from the *isotropic space* to the *anisotropic space* by computing:

$$X = X_m(RT)^{-1}$$

Value

An $n \times 2$ matrix with the transformed coordinates.

**coords2coords**

**Operations on Coordinates**

**Description**

Functions for shifting, zooming and envolving rectangle of a set of coordinates.

**Usage**

```r
coords2coords(coords, xlim, ylim, xlim ori, ylim ori)
zoom.coords(x, ...)
```

**Arguments**

- **coords**: two column matrix or data-frame with coordinates.
- **xlim**: range of the new x-coordinates.
- **ylim**: range of the new y-coordinates.
coords2coords

```
xlim.ori  optional. Range of the original x-coordinates, by default the range of the original x-coordinates.
ylim.ori  optional. Range of the original y-coordinates, by default the range of the original y-coordinates.
xzoom    scalar, expanding factor in the x-direction.
yzoom    scalar, expanding factor in the y-direction.
xoff     scalar, shift in the x-direction.
yoff     scalar, shift in the y-direction.
add.to.plot logical, if TRUE the rectangle is added to the current plot.
quiet    logical, none is returned.
...      further arguments to be passed to rect.
```

**Value**

- `coords2coords` and `zoom.coords`
  - return an object of the same type as given in the argument `coords` with the transformed coordinates.
- `rect.coords`
  - returns a matrix with the 4 coordinates of the rectangle defined by the coordinates.

**Author(s)**

Paulo Justiniano Ribeiro Jr. `<paulojus@leg.ufpr.br>`,
Peter J. Diggle `<p.diggle@lancaster.ac.uk>`.

**See Also**

- `subarea`, `rect`

arrows(foo[,1], foo[,2], foo2[,1], foo2[,2])
legend("topleft",
c("foo", "foo1 (zoom.coords)", "foo2 (coords2coords)"), lty=c(1,2,1), lwd=c(1,1,2))
```

```r
## "zooming" part of The Gambia map
gb <- gambia.borders/1000
gd <- gambia[,1:2]/1000
```
cov.spatial

Computes Value of the Covariance Function

Description

Computes the covariances for pairs of variables, given the separation distance of their locations. Options for different correlation functions are available. The results can be seen as a change of metric, from the Euclidean distances to covariances.

Usage

cov.spatial(obj, cov.model= "matern",
            cov.pars=stop("no cov.pars argument provided"),
            kappa = 0.5)

Arguments

obj a numeric object (vector or matrix), typically with values of distances between pairs of spatial locations.

cov.model string indicating the type of the correlation function. Available choices are: "matern", "exponential", "gaussian", "spherical", "circular", "cubic", "wave", "power", "powered.exponential", "cauchy", "gencauchy", "gneiting", "gneiting.matern", "pure.nugget". See section DETAILS for available options and expressions of the correlation functions.

cov.pars a vector with 2 elements or an \(n \times 2\) matrix with the covariance parameters. The first element (if a vector) or first column (if a matrix) corresponds to the variance parameter \(\sigma^2\). The second element or column corresponds to the range parameter \(\phi\) of the correlation function. If a matrix is provided, each row corresponds to the parameters of one spatial structure (see DETAILS below).

kappa numerical value for the additional smoothness parameter of the correlation function. Only required by the following correlation functions: "matern", "powered.exponential", "cauchy", "gencauchy" and "gneiting.matern".
Details

Covariance functions return the value of the covariance $C(h)$ between a pair variables located at points separated by the distance $h$. The covariance function can be written as a product of a variance parameter $\sigma^2$ times a positive definite correlation function $\rho(h)$:

$$C(h) = \sigma^2 \rho(h).$$

The expressions of the covariance functions available in geoR are given below. We recommend the LaTeX (and/or the corresponding .dvi, .pdf or .ps) version of this document for better visualization of the formulas.

Denote $\phi$ the basic parameter of the correlation function and name it the range parameter. Some of the correlation functions will have an extra parameter $\kappa$, the smoothness parameter. $K_\kappa(x)$ denotes the modified Bessel function of the third kind of order $\kappa$. See documentation of the function besselK for further details. In the equations below the functions are valid for $\phi > 0$ and $\kappa > 0$, unless stated otherwise.

cauay

$$\rho(h) = [1 + (\frac{h}{\phi})^2]^{-\kappa}$$

geneauay (generalised Cauchy)

$$\rho(h) = [1 + (\frac{h}{\phi})^{\kappa_2}]^{-\kappa_1/\kappa_2}, \kappa_1 > 0, 0 < \kappa_2 \leq 2$$

circular

Let $\theta = \min(\frac{h}{\phi},1)$ and

$$g(h) = 2(\frac{\theta \sqrt{1-\theta^2} + \sin^{-1} \sqrt{\theta}}{\pi}).$$

Then, the circular model is given by:

$$\rho(h) = \begin{cases} 1 - g(h), & \text{if } h < \phi \\ 0, & \text{otherwise}\end{cases}$$

cubic

$$\rho(h) = \begin{cases} 1 - \left[7(\frac{h}{\phi})^2 - 8.75(\frac{h}{\phi})^3 + 3.5(\frac{h}{\phi})^5 - 0.75(\frac{h}{\phi})^7\right], & \text{if } h < \phi \\ 0, & \text{otherwise}\end{cases}$$

gaussian

$$\rho(h) = \exp[-(\frac{h}{\phi})^2]$$

exponential

$$\rho(h) = \exp(-\frac{h}{\phi})$$
matern

\[ \rho(h) = \frac{1}{2^{\kappa-1} \Gamma(\kappa)} \left( \frac{h}{\phi} \right)^\kappa K_\kappa \left( \frac{h}{\phi} \right) \]

spherical

\[ \rho(h) = \begin{cases} 
1 - 1.5 \frac{h}{\phi} + 0.5 \left( \frac{h}{\phi} \right)^3, & \text{if } h < \phi \\
0, & \text{otherwise} 
\end{cases} \]

power (and linear)

The parameters of the this model \( \sigma^2 \) and \( \phi \) can not be interpreted as partial sill and range as for the other models. This model implies an unlimited dispersion and, therefore, has no sill and corresponds to a process which is only intrinsically stationary. The variogram function is given by:

\[ \gamma(h) = \sigma^2 h^\phi, \quad 0 < \phi < 2, \quad \sigma^2 > 0 \]

Since the corresponding process is not second order stationary the covariance and correlation functions are not defined. For internal calculations the geoR functions uses the fact the this model possesses locally stationary representations with covariance functions of the form:

\[ C(h) = \sigma^2 (A - h^\phi), \]

where \( A \) is a suitable constant as given in Chilès \& Delfiner (pag. 511, eq. 7.35).

The linear model corresponds a particular case with \( \phi = 1 \).

powered.exponential (or stable)

\[ \rho(h) = \exp\left[-\left( \frac{h}{\phi} \right)^\kappa \right], \quad 0 < \kappa \leq 2 \]

gneiting

\[ C(h) = (1 + 8sh + 25(sh)^2 + 32(sh)^3) (1 - sh)^8 1_{[0,1]}(sh) \]

where \( s = 0.301187465825 \). For further details see documentation of the function CovarianceFct in the package RandomFields from where we extract the following: “It is an alternative to the gaussian model since its graph is visually hardly distinguishable from the graph of the Gaussian model, but possesses neither the mathematical and nor the numerical disadvantages of the Gaussian model.”

gneiting.matern

Let \( \alpha = \phi \kappa_2, \rho_m(\cdot) \) denotes the Matérn model and \( \rho_g(\cdot) \) the Gneiting model. Then the Gneiting-Matérn is given by

\[ \rho(h) = \rho_g(h|\phi = \alpha) \rho_m(h|\phi = \phi, \kappa = \kappa_1) \]

wave

\[ \rho(h) = \frac{\phi}{h} \sin\left( \frac{h}{\phi} \right) \]
pure.nugget

\[ \rho(h) = k \]

where \( k \) is a constant value. This model corresponds to no spatial correlation.

**Nested models** Models with several structures usually called *nested models* in the geostatistical literature are also allowed. In this case the argument `cov.pars` takes a matrix and `cov.model` and `lambda` can either have length equal to the number of rows of this matrix or length 1. For the latter `cov.model` and/or `lambda` are recycled, i.e. the same value is used for all structures.

**Value**

The function returns values of the covariances corresponding to the given distances. The type of output is the same as the type of the object provided in the argument `obj`, typically a vector, matrix or array.

**Examples**

```r
# Variogram models with the same "practical" range:
#
v.f <- function(x, ...){1-cov.spatial(x, ...)}
#
curve(v.f(x, cov.pars=c(1, .2)), from = 0, to = 1,
    xlab = "distance", ylab = expression(gamma(h)),
    main = "variograms with equivalent "practical range\"")
curve(v.f(x, cov.pars = c(1, .6), cov.model = "sph"), 0, 1,
    add = TRUE, lty = 2)
```
curve(v.f(x, cov.pars = c(1, .6/sqrt(3)), cov.model = "gau"),
  0, 1, add = TRUE, lwd = 2)
legend("topleft", c("exponential", "spherical", "gaussian"),
  lty=c(1,2,1), lwd=c(1,1,2))
# # Matern models with equivalent "practical range"
# and varying smoothness parameter
# curve(v.f(x, cov.pars = c(1, .25), kappa = 0.5),from = 0, to = 1,
# xlab = "distance", ylab = expression(gamma(h)), lty = 2,
# main = "models with equivalent \"practical\" range")
curve(v.f(x, cov.pars = c(1, 0.188), kappa = 1),from = 0, to = 1,
  add = TRUE)
curve(v.f(x, cov.pars = c(1, 0.14), kappa = 2),from = 0, to = 1,
  add = TRUE, lwd=2, lty=2)
curve(v.f(x, cov.pars = c(1, 0.117), kappa = 2),from = 0, to = 1,
  add = TRUE, lwd=2)
legend("bottomright",
  expression(list(kappa == 0.5, phi == 0.250),
    list(kappa == 1, phi == 0.188), list(kappa == 2, phi == 0.140),
    list(kappa == 3, phi == 0.117)), lty=c(2,1,2,1), lwd=c(1,1,2,2))
# plotting a nested variogram model
curve(v.f(x, cov.pars = rbind(c(.4, .2), c(.6,.3)),
  cov.model = c("sph","exp")), 0, 1, ylab='nested model')

dup.coords  
Locates duplicated coordinates

Description
This function takes an object with 2-D coordinates and returns the positions of the duplicated coordinates. Also sets a method for duplicated

Usage

dup.coords(x, ...)
## Default S3 method:
dup.coords(x, ...)
## S3 method for class 'geodata'
dup.coords(x, incomparables, ...)
## S3 method for class 'geodata'
duplicated(x, incomparables, ...)

Arguments

x  a two column numeric matrix or data frame.
incomparables unused. Just for compatibility with the generic function duplicated.
... arguments passed to sapply. If simplify = TRUE (default) results are returned as an array if possible (when the number of replicates are the same at each replicated location)
Function and methods return NULL if there are no duplicates locations.

Otherwise, the default method returns a list where each component is a vector with the positions or the rownames, if available, of the duplicates coordinates.

The method for geodata returns a data-frame with rownames equals to the positions of the duplicated coordinates, the first column is a factor indicating duplicates and the remaining are output of \texttt{as.data.frame.geodata}.

**Author(s)**

Paulo Justiniano Ribeiro Jr. \texttt{<paulojus@leg.ufpr.br>}
Peter J. Diggle \texttt{<p.diggle@lancaster.ac.uk>}

**See Also**

\texttt{as.geodata} for the definition of geodata class, \texttt{duplicated} for the base function to identify duplicated values and \texttt{jitterDupCoords} for a function which jitters duplicated coordinates.

**Examples**

```r
## simulating data
dt <- grf(30, cov.p=c(1, .3))
## "forcing" some duplicated locations
dt$coords[17,] <- dt$coords[23,] <- dt$coords[8,]
## output of the method for geodata
dup.coords(dt)
## which is the same as a method for duplicated()
duplicated(dt)
## the default method:
dup.coords(dt$coords)
```

---

**Description**

Surface elevation data taken from Davis (1972). An object of the class geodata with elevation values at 52 locations.

**Usage**

data(elevation)
**Format**

An object of the class `geodata` which is a list with the following elements:

- `coords` x-y coordinates (multiples of 50 feet).
- `data` elevations (multiples of 10 feet).

**Source**

Davis, J.C. (1973) *Statistics and Data Analysis in Geology*. Wiley.

**Examples**

```r
summary(elevation)
plot(elevation)
```

---

**eyefit**

*Interactive Variogram Estimation*

**Description**

Function to fit an empirical variogram "by eye" using an interactive Tcl-Tk interface.

**Usage**

```r
eyefit(vario, silent = FALSE)
```

**Arguments**

- `vario` An empirical variogram object as returned by the function `variog`.
- `silent` logical indicating whether or not the fitted variogram must be returned.

**Value**

Returns a list of list with the model parameters for each of the saved fit(s).

**Author(s)**

Andreas Kiefer &lt;andreas@inf.ufpr.br&gt;
Paulo Justiniano Ribeiro Junior &lt;paulojus@leg.ufpr.br&gt;.

**See Also**

`variofit` for least squares variogram fit, `likfit` for likelihood based parameter estimation and `krige.bayes` to obtain the posterior distribution for the model parameters.
Description

Malaria prevalence in children recorded at villages in The Gambia, Africa.

Usage

data(gambia)

Format

Two objects are made available:

1. gambia
   A data frame with 2035 observations on the following 8 variables.
   - x x-coordinate of the village (UTM).
   - y y-coordinate of the village (UTM).
   - pos presence (1) or absence (0) of malaria in a blood sample taken from the child.
   - age age of the child, in days
   - netuse indicator variable denoting whether (1) or not (0) the child regularly sleeps under a bed-net.
   - treated indicator variable denoting whether (1) or not (0) the bed-net is treated (coded 0 if netuse=0).
   - green satellite-derived measure of the green-ness of vegetation in the immediate vicinity of the village (arbitrary units).
   - phc indicator variable denoting the presence (1) or absence (0) of a health center in the village.

2. gambia.borders
   A data frame with 2 variables:
   - x x-coordinate of the country borders.
   - y y-coordinate of the country borders.

References

Examples

```r
plot(gambia.borders, type="l", asp=1)
points(gambia[,1:2], pch=19)
# a built-in function for a zoomed map
gambia.map()
# Building a "village-level" data frame
ind <- paste("x", gambia[,1], "y", gambia[,2], sep="")
village <- gambia[duplicated(ind),c(1:2,7:8)]
village$prev <- as.vector(tapply(gambia$pos, ind, mean))
plot(village$green, village$prev)
```

---

**geoR-defunct  Defunct Functions in the Package geoR**

**Description**

The functions listed here are no longer part of the package `geoR` as they are not needed (any more).

**Usage**

```r
geoRdefunct()
```

**Details**

The following functions are now defunct:

1. `olsfit` functionality incorporated by `variofit`. From `geoR_1.0-6`.
2. `wlsfit` functionality incorporated by `variofit`. From `geoR_1.0-6`.
3. `likfit.old` functionality incorporated by `likfit`. From `geoR_1.0-6`. The associated functions were also made defunct:
   - `likfit.nospatial`, `loglik.spatial`, `proflik.nug`, `proflik.phi`, `proflik.ftau`.
4. `distdiag` functionally is redundant with `dist`.

**See Also**

`variofit`
globalvar  Computes global variance

Description

Global variance computation for a set of locations using the covariance model

Usage

globalvar(geodata, locations, coords = geodata$coords, krige)

Arguments

geodata  an object of the class geodata
locations  n by 2 matrix with a set of locations, typically a prediction grid
coords  data coordinates
krige  a list defining the model components and the type of kriging. It can take an output to a call to krige.control or a list with elements as for the arguments in krige.control.

Value

An scalar with the value of the global variance

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

See Also

krige.conv for the kriging algorithm.
Simulation of Gaussian Random Fields

**Description**

`grf()` generates (unconditional) simulations of Gaussian random fields for given covariance parameters. `geoR2RF` converts model specification used by `geoR` to the corresponding one in `RandomFields`.

**Usage**

```r
grf(n, grid = "irreg", nx, ny, xlims = c(0, 1), ylims = c(0, 1),
    borders, nsim = 1, cov.model = "matern",
    cov.pars = stop("missing covariance parameters sigmasq and phi"),
    kappa = 0.5, nugget = 0, lambda = 1, aniso.pars,
    mean = 0, method, RF=TRUE, messages)
```

`geoR2RF(cov.model, cov.pars, nugget = 0, kappa, aniso.pars)`

**Arguments**

- `n`: number of points (spatial locations) in each simulations.
- `grid`: optional. An $n \times 2$ matrix with coordinates of the simulated data.
- `nx`: optional. Number of points in the X direction.
- `ny`: optional. Number of points in the Y direction.
- `xlims`: optional. Limits of the area in the X direction. Defaults to $[0, 1]$.
- `ylims`: optional. Limits of the area in the Y direction. Defaults to $[0, 1]$.
- `borders`: optional. Typically a two columns matrix specifying a polygon. See DETAILS below.
- `nsim`: Number of simulations. Defaults to 1.
- `cov.model`: correlation function. See `cov.spatial` for further details. Defaults to the exponential model.
- `cov.pars`: a vector with 2 elements or an $n \times 2$ matrix with values of the covariance parameters $\sigma^2$ (partial sill) and $\phi$ (range parameter). If a vector, the elements are the values of $\sigma^2$ and $\phi$, respectively. If a matrix, corresponding to a model with several structures, the values of $\sigma^2$ are in the first column and the values of $\phi$ are in the second.
- `kappa`: additional smoothness parameter required only for the following correlation functions: "matern", "powered.exponential", "cauchy" and "gneiting.matern". More details on the documentation for the function `cov.spatial`.
- `nugget`: the value of the nugget effect parameter $\tau^2$.
- `lambda`: value of the Box-Cox transformation parameter. The value $\lambda = 1$ corresponds to no transformation, the default. For any other value of $\lambda$ Gaussian data is simulated and then transformed.
aniso.pars: geometric anisotropy parameters. By default an isotropic field is assumed and this argument is ignored. If a vector with 2 values is provided, with values for the anisotropy angle $\psi_A$ (in radians) and anisotropy ratio $\psi_A$, the coordinates are transformed, the simulation is performed on the isotropic (transformed) space and then the coordinates are back-transformed such that the resulting field is anisotropic. Coordinates transformation is performed by the function `coords.aniso`.

mean: a numerical vector, scalar or the same length of the data to be simulated. Defaults to zero.

method: simulation method with options for "cholesky", "svd", "eigen", "RF". Defaults to the Cholesky decomposition. See section DETAILS below.

RF: logical, with defaults to TRUE, indicating whether the algorithm should try to use the function GaussRF from the package RandomFields in case of method is missing and the number of points is greater than 500.

messages: logical, indicating whether or not status messages are printed on the screen (or output device) while the function is running. Defaults to TRUE.

Details

For the methods "cholesky", "svd" and "eigen" the simulation consists of multiplying a vector of standardized normal deviates by a square root of the covariance matrix. The square root of a matrix is not uniquely defined. These three methods differs in the way they compute the square root of the (positive definite) covariance matrix.

The previously available method method = "circular.embedding" is no longer available in geoR. For simulations in a fine grid and/or with a large number of points use the package RandomFields.

The option "RF" calls internally the function GaussRF from the package RandomFields.

The argument borders, if provides takes a polygon data set following argument poly for the splancs' function csr, in case of grid="reg" or gridpts, in case of grid="irreg". For the latter the simulation will have approximately “n” points.

Value

`grf` returns a list with the components:

- `coords`: an $n \times 2$ matrix with the coordinates of the simulated data.
- `data`: a vector (if nsim = 1) or a matrix with the simulated values. For the latter each column corresponds to one simulation.
- `cov.model`: a string with the name of the correlation function.
- `nugget`: the value of the nugget parameter.
- `cov.pars`: a vector with the values of $\sigma^2$ and $\phi$, respectively.
- `kappa`: value of the parameter $\kappa$.
- `lambda`: value of the Box-Cox transformation parameter $\lambda$.
- `aniso.pars`: a vector with values of the anisotropy parameters, if provided in the function call.
- `method`: a string with the name of the simulation method used.
grf

sim.dim a string "1d" or "2d" indicating the spatial dimension of the simulation.
.RANDOM.seed the random seed by the time the function was called.
messages messages produced by the function describing the simulation.
call the function call.

geoR2grf returns a list with the components:

model RandomFields name of the correlation model
param RandomFields parameter vector

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

###

**head**

*Head observations in a regional confined aquifer*

**Description**

Measurements of potentiometric head at 29 locations in a regional confined sandstone aquifer. Extract from Kitanidis’ book.

**Usage**

data(head)

**Format**

An object of the class *geodata* which is a list with the elements:

- **coords** coordinates of the data location.
- **data** the data vector with head measurements (feet).

**Source**

**Examples**

summary(head)
plot(head)
hist.krige.bayes  
Plots Sample from Posterior Distributions

Description
Plots histograms and/or density estimation with samples from the posterior distribution of the model parameters

Usage
```r
## S3 method for class 'krige.bayes'
hist(x, pars, density.est = TRUE, histogram = TRUE, ...)
```

Arguments
- `x`: an object of the class `krige.bayes`, with an output of the functions `krige.bayes`.
- `pars`: a vector with the names of one or more of the model parameters. Defaults to all model parameters. Setting to -1 excludes the intercept.
- `density.est`: logical indication whether a line with the density estimation should be added to the plot.
- `histogram`: logical indicating whether the histogram is included in the plot.
- `...`: further arguments for the plotting functions and or for the density estimation.

Value
Produces a plot in the currently graphics device.
Returns an `invisible` list with the components:

- `histogram`: with the output of the function `hist` for each parameter
- `density.estimation`: with the output of the function `density` for each parameter

Author(s)
Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

The hoef data frame has 25 rows and 5 columns. The data consists of a uniformity trial for which artificial treatment effects were assign to the plots.

This data frame contains the following columns:

- **x1** x-coordinate of the plot.
- **x2** y-coordinate of the plot.
- **dat** the artificial data.
- **trat** the treatment number.
- **ut** the data from the uniformity trial, without the treatment effect.

The treatment effects assign to the plots are:

- Treatment 1: $\tau_1 = 0$
- Treatment 2: $\tau_2 = -3$
- Treatment 3: $\tau_3 = -5$
- Treatment 4: $\tau_4 = 6$
- Treatment 5: $\tau_5 = 6$

```
hoef.geo <- as.geodata(hoef, covar.col=4)
summary(hoef)
summary(hoef.geo)
points(hoef.geo, cex.min=2, cex.max=2, pt.div="quintiles")
```
Description

Methods for image, contour or perspective plot of a realisation of a Gaussian random field, simulated using the function `grf`.

Usage

```r
## S3 method for class 'grf'
image(x, sim.number = 1, borders, x.leg, y.leg, ...)
## S3 method for class 'grf'
contour(x, sim.number = 1, borders, filled = FALSE, ...)
## S3 method for class 'grf'
persp(x, sim.number = 1, borders, ...)
```

Arguments

- `x` an object of the class `grf`, typically an output of the function `grf`.
- `sim.number` simulation number. Indicates the number of the simulation to be plotted. Only valid if the object contains more than one simulation. Defaults to 1.
- `borders` optional. Typically a two columns matrix specifying a polygon. Points outside the borders will be set to `NA`.
- `x.leg, y.leg` limits for the legend in the horizontal and vertical directions.
- `filled` logical. If `FALSE` the function `contour` is used otherwise `filled.contour`. Defaults to `FALSE`.
- `...` further arguments to be passed to the functions `image`, `contour` or `persp`.

Value

An image or perspective plot is produced on the current graphics device. No values are returned.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information about the package `geoR` can be found at:

http://www.leg.ufpr.br/geoR.

See Also

`grf` for simulation of Gaussian random fields, `image` and `persp` for the generic plotting functions.
Examples

```r
# generating 4 simulations of a Gaussian random field
sim <- grf(441, grid="reg", cov.pars=c(1, .25), nsim=4)
op <- par(no.readonly = TRUE)
par(mfrow=c(2,2), mar=c(3,3,1,1), mgp = c(2,1,0))
for (i in 1:4)
  image(sim, sim.n=i)
pard
```

Description

This function produces an image or perspective plot of a selected element of the predictive distribution returned by the function `krige.bayes`.

Usage

```r
## S3 method for class 'krige.bayes'
image(x, locations, borders, values.to.plot=c("mean", "variance",
  "mean.simulations", "variance.simulations",
  "quantiles", "probabilities", "simulation"),
  number.col, coords.data, x.leg, y.leg, messages, ...)

## S3 method for class 'krige.bayes'
contour(x, locations, borders, values.to.plot = c("mean", "variance",
  "mean.simulations", "variance.simulations",
  "quantiles", "probabilities", "simulation"),
  filled=FALSE, number.col, coords.data, x.leg, y.leg, messages, ...)

## S3 method for class 'krige.bayes'
persp(x, locations, borders, values.to.plot=c("mean", "variance",
  "mean.simulations", "variance.simulations",
  "quantiles", "probabilities", "simulation"),
  number.col, messages, ...)
```

Arguments

- `x` an object of the class `krige.bayes`, typically an output of the function `krige.bayes`.
- `locations` an \( n \times 2 \) matrix with the coordinates of the prediction locations, which should define a regular grid in order to be plotted by `image` or `persp`. By default does not need to be provided and evaluates the attribute "prediction.locations" from the input object.
borders an $n \times 2$ matrix with the coordinates defining the borders of a region inside the grid defined by locations. Elements in the argument values are assigned to locations internal to the borders and NA's to the external ones.

values.to.plot select the element of the predictive distribution to be plotted. See DETAILS below.

filled logical. If FALSE the function contour is used otherwise filled.contour. Defaults to FALSE.

number.col Specifies the number of the column to be plotted. Only used if previous argument is set to one of “quantiles”, ”probabilities” or ”simulation”.

coords.data optional. If an $n \times 2$ matrix with the data coordinates is provided, points indicating the data locations are included in the plot.

x.leg, y.leg limits for the legend in the horizontal and vertical directions.

messages logical, if TRUE status messages are printed while running the function.

... extra arguments to be passed to the plotting function image or persp.

Details

The function krige.bayes returns summaries and other results about the predictive distributions. The argument values.to.plot specifies which result will be plotted. It can be passed to the function in two different forms:

- a vector with the object containing the values to be plotted, or
- one of the following options: ”moments.mean”, ”moments.variance”, ”mean.simulations”, ”variance.simulations”, ”quantiles”, ”probability” or ”simulation”.

For the last three options, if the results are stored in matrices, a column number must be provided using the argument number.col.

The documentation for the function krige.bayes provides further details about these options.

Value

An image or persp plot is produced on the current graphics device. No values are returned.

image.kriging

Image or Perspective Plot with Kriging Results

Description

Plots image or perspective plots with results of the kriging calculations.

Usage

## S3 method for class 'kriging'
image(x, locations, borders, values = x$predict,
     coords.data, x.leg, y.leg, ...)

## S3 method for class 'kriging'
contour(x, locations, borders, values = x$predict,
     coords.data, filled=FALSE, ...)

## S3 method for class 'kriging'
persp(x, locations, borders, values = x$predict, ...)

Arguments

x
an object of the class kriging, typically with the output of the functions krige.conv or ksline.

locations
an \( n \times 2 \) matrix with the coordinates of the prediction locations, which should define a regular grid in order to be plotted by image or persp. By default does not need to be provided and evaluates the attribute "prediction.locations" from the input object.

borders
an \( n \times 2 \) matrix with the coordinates defining the borders of a region inside the grid defined by locations. Elements in the argument values are assigned to locations internal to the borders and NA’s to the external ones.

values
a vector with values to be plotted. Defaults to obj$predict.

coords.data
optional. If an \( n \times 2 \) matrix with the data coordinates is provided, points indicating the data locations are included in the plot.

x.leg, y.leg
limits for the legend in the horizontal and vertical directions.

filled
logical. If FALSE the function contour is used otherwise filled.contour. Defaults to FALSE.

...

further arguments to be passed to the functions image, contour, filled.contour, persp or legend.krig. For instance, the argument zlim can be used to set the the minimum and maximum ‘z’ values for which colors should be plotted. See documentation for those function for possible arguments.
Details

plot1d and prepare.graph.kriging are auxiliary functions called by the others.

Value

An image or perspective plot is produced on the current graphics device. No values are returned.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

krige.conv and ksline for kriging calculations. Documentation for image, contour, filled.contour and persp contain basic information on the plotting functions.

Examples

```r
loci <- expand.grid(seq(0,1,l=51), seq(0,1,l=51))
kc <- krige.conv(s100, loc=loci,
                 krig=krige.control(cov.pars=c(1, .25)))
image(kc)
contour(kc)
image(kc)
contour(kc, add=TRUE, nlev=21)
persp(kc, theta=20, phi=20)
contour(kc, filled=TRUE)
contour(kc, filled=TRUE, color=terrain.colors)
contour(kc, filled=TRUE, col=gray(seq(1,0,1=21)))
# adding data locations
image(kc, coords.data=s100$coords)
contour(kc,filled=TRUE,coords.data=s100$coords,color=terrain.colors)
# # now dealing with borders
#
bor <- matrix(c(.4,.1,.3,.9,.9,.7,.7,.3,.2,.5,.8),
              ncol=2)
# plotting just inside borders
image(kc, borders=bor)
contour(kc, borders=bor)
image(kc, borders=bor)
contour(kc, borders=bor, add=TRUE)
contour(kc, borders=bor, filled=TRUE, color=terrain.colors)
# kriging just inside borders
kcl <- krige.conv(s100, loc=loci,
                  krig=krige.control(cov.pars=c(1, .25)))
image(kcl)
contour(kcl, add=TRUE, nlev=21)
persp(kc, theta=20, phi=20)
contour(kc, filled=TRUE, color=terrain.colors)
```
InvChisquare

The (Scaled) Inverse Chi-Squared Distribution

Description
Density and random generation for the scaled inverse chi-squared ($\chi^2_{ScI}$) distribution with df degrees of freedom and optional non-centrality parameter scale.

Usage

dinvchisq(x, df, scale, log = FALSE)
ninvchisq(n, df, scale = 1/df)

Arguments

x vector of quantiles.
n number of observations. If length(n) > 1, the length is taken to be the number required.
df degrees of freedom.
scale scale parameter.
log logical; if TRUE, densities d are given as log(d).
Details

The inverse chi-squared distribution with \( df = n \) degrees of freedom has density

\[
f(x) = \frac{1}{2^{n/2} \Gamma(n/2)} \left( \frac{1}{x} \right)^{n/2 + 1} e^{-1/(2x)}
\]

for \( x > 0 \). The mean and variance are \( \frac{1}{n-2} \) and \( \frac{2}{(n-4)(n-2)} \).

The non-central chi-squared distribution with \( df = n \) degrees of freedom and non-centrality parameter \( \lambda = S^2 \) has density

\[
f(x) = \frac{n/2^{n/2}}{\Gamma(n/2)} S^n \left( \frac{1}{x} \right)^{n/2 + 1} e^{-(nS^2)/(2x)}
\]

, for \( x \geq 0 \). The first is a particular case of the latter for \( \lambda = n/2 \).

Value

dinvchisq gives the density and rinvchisq generates random deviates.

See Also

rchisq for the chi-squared distribution which is the basis for this function.

Examples

```r
set.seed(1234); rinvchisq(5, df=2)
set.seed(1234); 1/rchisq(5, df=2)
set.seed(1234); rinvchisq(5, df=2, scale=5)
set.seed(1234); 5*2/rchisq(5, df=2)

## inverse Chi-squared is a particular case
x <- 1:10
all.equal(dinvchisq(x, df=2), rinvchisq(x, df=2, scale=1/2))
```

Description

Toy example used in the book *An Introduction to Geostatistics* to illustrate the effects of different models and parameters in the kriging results when predicting at a given point.

Usage

```r
data(isaaks)
```
**jitterDupCoords**

**Format**

An object of the class `geodata` which is a list with the elements:

- `coords` coordinates of the data location.
- `data` the data vector.
- `x0` coordinate of the prediction point.

**Source**

**Examples**

```r
isaaks
summary(isaaks)
plot(isaaks$coords, asp=1, type="n")
points(isaaks$x0, pch="?", cex=2, col=2)
```

---

**Description**

Jitters 2D coordinates uniformly on a region around (duplicated) points.

**Usage**

```r
jitter2d(coords, max, min = 0.2 * max, fix.one = TRUE,
         which.fix = c("random", "first", "last"))

jitterDupCoords(x, ...)
```

## Default S3 method:

```r
jitterDupCoords(x, ...)
```

## S3 method for class 'geodata'

```r
jitterDupCoords(x, ...)
```

**Arguments**

- `x, coords` a matrix or data frame with 2D coordinates or geodata object.
- `max` numeric scalar defining maximum jittering distance.
- `min` numeric scalar defining minimum jittering distance.
kattegat

fix.one logical. Whether or not one of the coordinates should not be jittered.
which.fix single element vector of integer or character, defining which coordinate won't be jittered. Only used if fix.one=TRUE.
...
arguments passed to jitter2d.

Value

jitter2d returns an object of the same type fo the input with jittered values
jitterDupCoords returns an object of the same type fo the input with jittered coordinate values only at the duplicated locations

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

See Also

dup.coords, duplicated.geodata for functions identifying duplicated locations.

Examples

## simulating data
dt <- grf(30, cov.p=c(1,.3))
dt$coords <- round(dt$coords, dig=2)
## "forcing" some duplicated locations
dt$coords[17,] <- dt$coords[23,] <- dt$coords[8,]

dt$coords[c(2,4,14,24),]
jitter2d(dt$coords[c(2,4,14,24),], max=0.01)

## jittering only the duplicated locations and comparing with original
cbind(dt$coords, jitterDupCoords(dt$coords, max=0.01))

## creating a now geodata object jittering the duplicated locations of the original one:
dup.coords(dt)
dt1 <- jitterDupCoords(dt, max=0.01)
dup.coords(dt1)

---

**kattegat**

*Kattegat basin salinity data*

Description

Salinity measurements at the Kattegat basin, Denmark.
Usage

data(kattegat)

Format

An object of the class "geodata", which is list with three components:

- coords: the coordinates of the data locations. The distance are given in kilometers.
- data: values of the piezometric head. The unit is heads to meters.
- dk: a list with coordinates of lines defining borders and islands across the study area.

Source

National Environmental Research Institute, Arhus University, Denmark and the Swedish Meteorological and Hydrological Institute.

References

Examples

```r
plot(c(550,770),c(6150,6420),type="n",xlab="X UTM",ylab="Y UTM")
points(kattegat, add=TRUE)
lapply(kattegat$dk, lines, lwd=2)
```

Description

The function `krige.bayes` performs Bayesian analysis of geostatistical data allowing specifications of different levels of uncertainty in the model parameters. It returns results on the posterior distributions for the model parameters and on the predictive distributions for prediction locations (if provided).

Usage

```r
krige.bayes(geodata, coords = geodata$coords, data = geodata$data, 
  locations = "no", borders, model, prior, output)
model.control(trend.d = "cte", trend.l = "cte", cov.model = "matern", 
  kappa = 0.5, aniso.pars = NULL, lambda = 1)
prior.control(beta.prior = c("flat", "normal", "fixed"),
  beta = NULL, beta.var.std = NULL,
```
Arguments

geodata a list containing elements coords and data as described next. Typically an object of the class "geodata" - a geoR data-set. If not provided the arguments coords and data must be provided instead.

coords an \(n \times 2\) matrix where each row has the 2-D coordinates of the \(n\) data locations. By default it takes the component coords of the argument geodata, if provided.

data a vector with \(n\) data values. By default it takes the component data of the argument geodata, if provided.

locations an \(N \times 2\) matrix or data-frame with the 2-D coordinates of the \(N\) prediction locations, or a list for which the first two components are used. Input is internally checked by the function check.locations. Defaults to "no" in which case the function returns only results on the posterior distributions of the model parameters.

borders optional. If missing, by default reads the element borders from the geodata object, if present. Setting to NULL preents this behavior. If a two column matrix defining a polygon is provided the prediction is performed only at locations inside this polygon.

model a list defining the fixed components of the model. It can take an output to a call to model.control or a list with elements as for the arguments in model.control. Default values are assumed for arguments not provided. See section DETAILS below.

prior a list with the specification of priors for the model parameters. It can take an output to a call to prior.control or a list with elements as for the arguments in prior.control. Default values are assumed for arguments not provided. See section DETAILS below.

output a list specifying output options. It can take an output to a call to output.control or a list with elements as for the arguments in output.control. Default values are assumed for arguments not provided. See documentation for output.control for further details.

trend.d specifies the trend (covariates) values at the data locations. See documentation of trend.spatial for further details. Defaults to "cte".

trend.l specifies the trend (covariates) at the prediction locations. Must be of the same type as defined for trend.d. Only used if prediction locations are provided in the argument locations.
cov.model string indicating the name of the model for the correlation function. Further
details in the documentation for cov.spatial.

kappa additional smoothness parameter. Only used if the correlation function is one
of: "matern", "powered.exponential", "cauchy" or "gneiting.matern".
In the current implementation this parameter is always regarded as fixed during
the Bayesian analysis.

aniso.pars fixed parameters for geometric anisotropy correction. If aniso.pars = FALSE
no correction is made, otherwise a two elements vector with values for the
anisotropy parameters must be provided. Anisotropy correction consists of
a transformation of the data and prediction coordinates performed by the function
coords.aniso.

lambda numerical value of the Box-Cox transformation parameter. The value \( \lambda = 1 \)
corresponds to no transformation. The Box-Cox parameter \( \lambda \) is always regarded
as fixed and data transformation is performed before the analysis. Prediction
results are back-transformed and returned is the same scale as for the original
data. For \( \lambda = 0 \) the log-transformation is performed. If \( \lambda < 0 \) the mean
predictor doesn't make sense (the resulting distribution has no expectation).

beta.prior prior distribution for the mean (vector) parameter \( \beta \). The options are "flat" (de-
default), "normal" or "fixed" (known mean).

beta mean hyperparameter for the distribution of the mean (vector) parameter \( \beta \).
Only used if beta.prior = "normal" or beta.prior = "fixed". For the
later beta defines the value of the known mean.

beta.var.std standardised (co)variance hyperparameter(s) for the prior for the mean (vector)
parameter \( \beta \). The (co)variance matrix for \( \beta \) is given by the multiplication of this
matrix by \( \sigma^2 \). Only used if beta.prior = "normal".

sigmasq.prior specifies the prior for the parameter \( \sigma^2 \). If "reciprocal" (the default), the prior
\( \frac{1}{\sigma^2} \) is used. Otherwise the parameter is regarded as fixed.

sigmasq fixed value of the sill parameter \( \sigma^2 \). Only used if sigmasq.prior = FALSE.

df.sigmasq numerical. Number of degrees of freedom for the prior for the parameter \( \sigma^2 \).
Only used if sigmasq.prior = "sc.inv.chisq".

phi.prior prior distribution for the range parameter \( \phi \). Options are: "uniform", "exponential",
"reciprocal", "squared.reciprocal" and "fixed". Alternatively, a user
defined discrete distribution can be specified. In this case the argument takes
a vector of numerical values of probabilities with corresponding support points
provided in the argument phi.discrete.
If "fixed" the argument \( \phi \) must be provided and is regarded as fixed when per-
forming predictions.
For the exponential prior the argument \( \phi \) must provide the value for of hyper-
parameter \( \nu \) which corresponds to the expected value for this distribution.

phi fixed value of the range parameter \( \phi \). Only needed if phi.prior = "fixed" or
if phi.prior = "exponential".

phi.discrete support points of the discrete prior for the range parameter \( \phi \). The default is a
sequence of 51 values between 0 and 2 times the maximum distance between
the data locations.
tausq.rel.prior

specifies a prior distribution for the relative nugget parameter \( \frac{\tau^2}{\sigma^2} \). If tausq.rel.prior = "fixed" the relative nugget is considered known (fixed) with value given by the argument tausq.rel. If tausq.rel.prior = "uniform" a discrete uniform prior is used with support points given by the argument tausq.rel.discrete. Alternatively, a user defined discrete distribution can be specified. In this case the argument takes the a vector of probabilities of a discrete distribution and the support points should be provided in the argument tausq.rel.discrete.

tausq.rel

fixed value for the relative nugget parameter. Only used if tausq.rel.prior = "fixed".

tausq.rel.discrete

support points of the discrete prior for the relative nugget parameter \( \frac{\tau^2}{\sigma^2} \).

obj

an object of the class krig.e.bayes or posterior.krig.e.bayes with the output of a call to krig.e.bayes. The function post2prior takes the posterior distribution computed by one call to krig.e.bayes and prepares it to be used a a prior in a subsequent call. Notice that in this case the function post2prior is used instead of prior.control.

Details

krige.bayes is a generic function for Bayesian geostatistical analysis of (transformed) Gaussian where predictions take into account the parameter uncertainty.

It can be set to run conventional kriging methods which use known parameters or plug-in estimates. However, the functions krig.e.conv and ksline are preferable for prediction with fixed parameters.

PRIOR SPECIFICATION

The basis of the Bayesian algorithm is the discretisation of the prior distribution for the parameters \( \phi \) and \( \tau_{rel}^2 = \frac{\tau^2}{\sigma^2} \). The Tech. Report (see References below) provides details on the results used in the current implementation.

The expressions of the implemented priors for the parameter \( \phi \) are:

"uniform": \( p(\phi) \propto 1 \).
"exponential": \( p(\phi) = \frac{1}{\nu} \exp(-\frac{1}{\nu} \phi) \).
"reciprocal": \( p(\phi) \propto \frac{1}{\phi} \).
"squared.reciprocal": \( p(\phi) \propto \frac{1}{\phi^2} \).
"fixed": fixed known or estimated value of \( \phi \).

The expressions of the implemented priors for the parameter \( \tau_{rel}^2 \) are:

"fixed": fixed known or estimated value of \( \tau_{rel}^2 \). Defaults to zero.
"uniform": \( p(\tau_{rel}^2) \propto 1 \).
"reciprocal": \( p(\tau_{rel}^2) \propto \frac{1}{\tau_{rel}^2} \).

Apart from those a user defined prior can be specified by entering a vector of probabilities for a discrete distribution with support points given by the argument phi.discrete and/or tausq.rel.discrete.

CONTROL FUNCTIONS
The function call includes auxiliary control functions which allows the user to specify and/or change the specification of model components (using `model.control`), prior distributions (using `prior.control`) and output options (using `output.control`). Default options are available in most of the cases.

**Value**

An object with class "krige.bayes" and "kriging". The attribute `prediction.locations` containing the name of the object with the coordinates of the prediction locations (argument `locations`) is assigned to the object. Returns a list with the following components:

- **posterior**: results on on the posterior distribution of the model parameters. A list with the following possible components:
  - beta summary information on the posterior distribution of the mean parameter $\beta$.
  - sigmasq summary information on the posterior distribution of the variance parameter $\sigma^2$ (partial sill).
  - phi summary information on the posterior distribution of the correlation parameter $\phi$ (range parameter).
  - tausq.rel summary information on the posterior distribution of the relative nugget variance parameter $\tau^2_{rel}$.
  - joint.phi.tausq.rel information on discrete the joint distribution of these parameters.
  - sample a data.frame with a sample from the posterior distribution. Each column corresponds to one of the basic model parameters.

- **predictive**: results on the predictive distribution at the prediction locations, if provided. A list with the following possible components:
  - mean expected values.
  - variance expected variance.
  - distribution type of posterior distribution.
  - mean.simulations mean of the simulations at each locations.
  - variance.simulations variance of the simulations at each locations.
  - quantiles.simulations quantiles computed from the simulations.
  - probabilities.simulations probabilities computed from the simulations.
  - simulations simulations from the predictive distribution.

- **prior**: a list with information on the prior distribution and hyper-parameters of the model parameters ($\beta, \sigma^2, \phi, \tau^2_{rel}$).

- **model**: model specification as defined by `model.control`.

- **.Random.seed**: system random seed before running the function. Allows reproduction of results. If the `.Random.seed` is set to this value and the function is run again, it will produce exactly the same results.

- **max.dist**: maximum distance found between two data locations.

- **call**: the function call.

**krige.conv**

**Spatial Prediction – Conventional Kriging**

**Description**

This function performs spatial prediction for fixed covariance parameters using global neighbourhood.

Options available implement the following types of kriging: *SK* (simple kriging), *OK* (ordinary kriging), *KTE* (external trend kriging) and *UK* (universal kriging).

**Usage**

```r
krige.conv(geodata, coords=geodata$coords, data=geodata$data,
locations, borders, krige, output)
```
krige.conv

krige.control(type.krige = "ok", trend.d = "cte", trend.l = "cte",
obj.model = NULL, beta, cov.model, cov.pars, kappa,
nugget, micro.scale = 0, dist.epsilon = 1e-10,
aniso.pars, lambda)

Arguments

geodata a list containing elements coords and data as described next. Typically an
object of the class "geodata" - a geoR data-set. If not provided the arguments
coords and data must be provided instead.

coops an $n \times 2$ matrix or data-frame with the 2-D coordinates of the $n$ data locations.
By default it takes the component coords of the argument geodata, if provided.
data a vector with $n$ data values. By default it takes the component data of the
argument geodata, if provided.

locations an $N \times 2$ matrix or data-frame with the 2-D coordinates of the $N$ prediction
locations, or a list for which the first two components are used. Input is internally
checked by the function check.locations.

borders optional. By default reads the element borders from the geodata object, if
present. Setting to NULL prevents this behavior. If a two column matrix defining
a polygon is provided the prediction is performed only at locations inside this
polygon.

krige a list defining the model components and the type of kriging. It can take an
output to a call to krige.control or a list with elements as for the arguments in
krige.control. Default values are assumed for arguments or list elements
not provided. See the description of arguments in `krige.control` below.

output a list specifying output options. It can take an output to a call to output.control
or a list with elements as for the arguments in output.control. Default values
are assumed for arguments not provided. See documentation for `output.control`
for further details.

type.krige type of kriging to be performed. Options are "SK", "OK" corresponding to
simple or ordinary kriging. Kriging with external trend and universal kriging
can be defined setting type.krige = "OK" and specifying the trend model
using the arguments trend.d and trend.l.

trend.d specifies the trend (covariate) values at the data locations. See documentation of
trend.spatial for further details. Defaults to "cte".

trend.l specifies the trend (covariate) values at prediction locations. It must be of the
same type as for trend.d. Only used if prediction locations are provided in the
argument locations.

obj.model a list with the model parameters. Typically an output of likfit or variofit.

beta numerical value of the mean (vector) parameter. Only used if type.krige="SK".

cov.model string indicating the name of the model for the correlation function. Further
details can be found in the documentation of the function cov.spatial.

cov.pars a 2 elements vector with values of the covariance parameters $\sigma^2$ (partial sill) and
$\phi$ (range parameter), respectively.
kappa additional smoothness parameter required by the following correlation functions: "matern", "powered.exponential", "cauchy" and "gneiting.matern".
nugget the value of the nugget variance parameter $\tau^2$. Defaults to zero.

micro.scale micro-scale variance. If different from zero, the nugget variance is divided into 2 terms: micro-scale variance and measurement error. This affect the precision of the predictions. Often in practice, these two variance components are indistinguishable but the distinction can be made here if justifiable. See the section DETAILS in the documentation of output.control.
dist.epsilon a numeric value. Locations which are separated by a distance less than this value are considered co-located.
aniso.pars parameters for geometric anisotropy correction. If aniso.pars = FALSE no correction is made, otherwise a two elements vector with values for the anisotropy parameters must be provided. Anisotropy correction consists of a transformation of the data and prediction coordinates performed by the function coords.aniso.

lambda numeric value of the Box-Cox transformation parameter. The value $\lambda = 1$ corresponds to no transformation and $\lambda = 0$ corresponds to the log-transformation. Prediction results are back-transformed and returned is the same scale as for the original data.

Details

According to the arguments provided, one of the following different types of kriging: SK, OK, UK or KTE is performed. Defaults correspond to ordinary kriging.

Value

An object of the class kriging. The attribute prediction.locations containing the name of the object with the coordinates of the prediction locations (argument locations) is assigned to the object. Returns a list with the following components:

- predict a vector with predicted values.
- kringe.var a vector with predicted variances.
- beta.est estimates of the $\beta$, parameter implicit in kriging procedure. Not included if type.kringe = "SK".
- simulations an $ni \times n.sim$ matrix where $ni$ is the number of prediction locations. Each column corresponds to a conditional simulation of the predictive distribution. Only returned if $n.sim > 0$.
- message messages about the type of prediction performed.
- call the function call.

Other results can be included depending on the options passed to output.control.

krweights

Description

Computes the weights assign for each data point in simple and ordinary kriging

Usage

krweights(coords, locations, krige)
**krweights**

Arguments

- **coords**: matrix with data coordinates
- **locations**: matrix with coordinates of the prediction points
- **krige**: kriging parameters. See krige.control in krige.conv

Value

A matrix of weights

Examples

```r
## Figure 8.4 in Webster and Oliver (2001), see help(wo)
attach(wo)
par(mfrow=c(2,2))
plot(c(-10,130), c(-10,130), ty="n", asp=1)
points(rbind(coords, x1))
KC1 <- krige.control(cov.pars=c(0.382,90.53))
w1 <- krweights(wo$coords, loc=x1, krige=KC1)
text(coords[,1], 5+coords[,2], round(w1, dig=3))
##

##
##
##
```
ksat

**Saturated Hydraulic Conductivity**

**Description**

The data consists of 32 measurements of the saturated hydraulic conductivity of a soil.

**Usage**

data(Ksat)

**Format**

The object `ksat` is a list of the class `geodata` with the following elements:

- `coords` a matrix with the coordinates of the soil samples.
- `data` measurements of the saturated hydraulic conductivity.
- `borders` a data-frame with the coordinates of a polygon defining the borders of the area.

**Source**

Data provided by Dr. Décio Cruciani, ESALQ/USP, Brasil.

**Examples**

summary(Ksat)
plot(Ksat, border=borders)

ksline

**Spatial Prediction – Conventional Kriging**

**Description**

This function performs spatial prediction for given covariance parameters. Options implement the following kriging types: SK (simple kriging), OK (ordinary kriging), KTE (external trend kriging) and UK (universal kriging).

The function `krige.conv` should be preferred, unless moving neighborhood is to be used.
ksline

Usage

ksline(geodata, coords = geodata$coords, data = geodata$data,
locations, borders = NULL,
cov.model = "matern",
cov.pars=stop("covariance parameters (sigmasq and phi) needed"),
kappa = 0.5, nugget = 0, micro.scale = 0,
lambda = 1, m0 = "ok", nwin = "full",
n.samples.backtransform = 500, trend = 1, d = 2,
ktedata = NULL, ktelocations = NULL, aniso.pars = NULL,
signal = FALSE, dist.epsilon = 1e-10, messages)

Arguments

geodata a list containing elements coords and data as described next. Typically an
object of the class "geodata" - a geoR data-set. If not provided the arguments
coods and data must be provided instead.

coords an n × 2 matrix where each row has the 2-D coordinates of the n data locations.
By default it takes the component coords of the argument geodata, if provided.
data a vector with n data values. By default it takes the component data of the
argument geodata, if provided.

locations an N × 2 matrix or data-frame with the 2-D coordinates of the N prediction
locations, or a list for which the first two components are used. Input is internally
checked by the function check.locations.

borders optional. If a two column matrix defining a polygon is provided the prediction
is performed only at locations inside this polygon.

cov.pars a vector with 2 elements or an n × 2 matrix with the covariance parameters σ^2
(partial sill) and φ (range parameter). If a vector, the elements are the values
of σ^2 and φ, respectively. If a matrix, corresponding to a model with several
structures, the values of σ^2 are in the first column and the values of φ are in the
second.

nugget the value of the nugget variance parameter τ^2. Defaults to zero.

micro.scale micro-scale variance. If different from zero, the nugget variance is divided into
2 terms: micro-scale variance and measurement error. This might affect the
precision of the predictions. In practice, these two variance components are
usually indistinguishable but the distinction can be made here if justifiable.

cov.model string indicating the name of the model for the correlation function. Further
details in the documentation for cov.spatial. Defaults are equivalent to the
exponential model.

kappa additional smoothness parameter required by the following correlation func-
tions: "matern", "powered.exponential", "cauchy" and "gneiting.matern".

lambda numeric value of the Box-Cox transformation parameter. The value λ = 1 cor-
responds to no transformation and λ = 0 corresponds to the log-transformation.
Prediction results are back-transformed and returned is the same scale as for the
original data.
The default value "ok" indicates that ordinary kriging will be performed. Other options are "kt" for kriging with a trend model (universal kriging) and "kte" for kriging with external trend (covariates). If a numeric value is provided it is assumed to be the value of a known mean and simple kriging is then performed. If "av" the arithmetic mean of the data is assumed to be the known mean for simple kriging algorithm.

If "full" global neighborhood is used i.e., all data values are used in the prediction of every prediction location. An integer number defines the moving neighborhood algorithm. The number provided is used as the number closest neighbors to be used for the prediction at each location. Defaults to "full".

number of samples used in the back-transformation. When transformations are used (specified by an argument lambda), back-transformations are usually performed by sampling from the predictive distribution and then back-transforming the sampled values. The exceptions are for \( \lambda = 0 \) (log-transformation) and \( \lambda = 1 \) (no transformation).

only required if \( m \) = "kt" (universal kriging). Possible values are 1 or 2, corresponding to a first or second degree polynomial trend on the coordinates, respectively.

spatial dimension, 1 defines a prediction on a line, 2 on a plane (the default).

only required if \( m \) = "kte". A vector or matrix with the values of the external trend (covariates) at the data locations.

only required if \( m \) = "kte". A vector or matrix with the values of the external trend (covariates) at the prediction locations.

parameters for geometric anisotropy correction. If \( \text{aniso.pars} = \text{FALSE} \) no correction is made, otherwise a two elements vector with values for the anisotropy parameters must be provided. Anisotropy correction consists of a transformation of the data and prediction coordinates performed by the function \text{coords.aniso}.

logical. If TRUE the signal is predicted, otherwise the variable is predicted. If no transformation is performed the expectations are the same in both cases and the difference is only for values of the kriging variance, if the value of the nugget is different from zero.

a numeric value. Points which are separated by a distance less than this value are considered co-located.

logical. Indicates whether or not status messages are printed on the screen (or other output device) while the function is running.

An object of the \text{class} \text{kriging} which is a list with the following components:

the predicted values.

the kriging variances.

the difference between the predicted value and the global mean. Represents the contribution to the neighboring data to the prediction at each point.
values of the arithmetic and weighted mean of the data and standard deviations. The weighted mean corresponds to the estimated value of the global mean.

ktrend the matrix with trend if m0 = "kt" (universal kriging).

ktetrend the matrix with trend if m0 = "kte" (external trend kriging).

beta the value of the mean which is implicitly estimated for m0 = "ok", "kte" or "kt".

wofmean weight of mean. The predicted value is an weighted average between the global mean and the values at the neighboring locations. The value returned is the weight of the mean.

locations the coordinates of the prediction locations.

message status messages returned by the algorithm.

call the function call.

Note

This is a preliminary and inefficient function implementing kriging methods. For predictions using global neighborhood the function krige.conv should be used instead.

landim1  
*Data from Landim’s book*

**Description**

Artificial or non-specified data from Paulo Landim’s book

**Usage**

```r
data(landim1)
```

**Format**

A data frame with 38 observations on the following 4 variables.

- **EW** a numeric vector with the east-west coordinates.
- **NS** a numeric vector with the north-south coordinates.
- **A** a numeric vector with data on a first variable.
- **B** a numeric vector with data on a second variable.

**Source**

```r
data(landim)
plot(as.geodata(landim1, data.col=3))
plot(as.geodata(landim1, data.col=4))
```

---

**legend.krige**  
*Add a legend to a image with kriging results*

**Description**

This function allows adds a legend to an image plot generated by `image.kriging` or `image.krige.bayes`. It can be called internally by these functions or directly by the user.

**Usage**

```r
legend.krige(x.leg, y.leg, values, scale.vals,
            vertical = FALSE, offset.leg = 1, ...)
```
Arguments

- `x.leg` limits for the legend in the $x$ direction.
- `y.leg` limits for the legend in the $y$ direction.
- `values` values plotted in the image.
- `scale.vals` optional. Values to appear in the legend. If not provided the function `pretty` is used to define the values.
- `vertical` If TRUE the legend is drawn in the vertical direction. Defaults to FALSE.
- `offset.leg` numeric value controlling the distance between the legend text and the legend box.
- `...` further arguments to be passed to the function `text`.

Value

A legend is added to the current plot. No values are returned.

## S3 method for class 'likGRF'
  fitted(object, spatial = TRUE, ...)

## S3 method for class 'likGRF'
  resid(object, spatial = FALSE, ...)

Arguments

geodata a list containing elements coords and data as described next. Typically an object of the class "geodata". If not provided the arguments coords and data must be provided instead.

coords an \( n \times 2 \) matrix where each row has the 2-D coordinates of the \( n \) data locations. By default it takes the component coords of the argument geodata, if provided.

data a vector with \( n \) data values. By default it takes the component data of the argument geodata, if provided.

trend specifies the mean part of the model. See documentation of trend.spatial for further details. Defaults to "cte".

ini.cov.pars initial values for the covariance parameters: \( \sigma^2 \) (partial sill) and \( \phi \) (range parameter). Typically a vector with two components. However a matrix can be used to provide several initial values. See DETAILS below.

fix.nugget logical, indicating whether the parameter \( \tau^2 \) (nugget variance) should be regarded as fixed (fix.nugget = TRUE) or should be estimated (fix.nugget = FALSE). Defaults to FALSE.

nugget value of the nugget parameter. Regarded as a fixed value if fix.nugget = TRUE otherwise as the initial value for the minimisation algorithm. Defaults to zero.

fix.kappa logical, indicating whether the extra parameter \( \kappa \) should be regarded as fixed (fix.kappa = TRUE) or should be estimated (fix.kappa = FALSE). Defaults to TRUE.

kappa value of the extra parameter \( \kappa \). Regarded as a fixed value if fix.kappa = TRUE otherwise as the initial value for the minimisation algorithm. Defaults to 0.5. This parameter is valid only if the covariance function is one of: "matern", "powered.exponential", "caucy" or "gneiting.matern". For more details on covariance functions see documentation for cov.spatial.

fix.lambda logical, indicating whether the Box-Cox transformation parameter \( \lambda \) should be regarded as fixed (fix.lambda = TRUE) or should be estimated (fix.lambda = FALSE). Defaults to TRUE.
lambda

value of the Box-Cox transformation parameter $\lambda$. Regarded as a fixed value if `fix.lambda = TRUE` otherwise as the initial value for the minimisation algorithm. Defaults to 1. Two particular cases are $\lambda = 1$ indicating no transformation and $\lambda = 0$ indicating log-transformation.

fix.psiA

logical, indicating whether the anisotropy angle parameter $\psi_A$ should be regarded as fixed (`fix.psiA = TRUE`) or should be estimated (`fix.psiA = FALSE`). Defaults to TRUE.

psiA

value (in radians) for the anisotropy angle parameter $\psi_A$. Regarded as a fixed value if `fix.psiA = TRUE` otherwise as the initial value for the minimisation algorithm. Defaults to 0. See `coords.aniso` for further details on anisotropy correction.

fix.psiR

logical, indicating whether the anisotropy ratio parameter $\psi_R$ should be regarded as fixed (`fix.psiR = TRUE`) or should be estimated (`fix.psiR = FALSE`). Defaults to TRUE.

psiR

value, always greater than 1, for the anisotropy ratio parameter $\psi_R$. Regarded as a fixed value if `fix.psiR = TRUE` otherwise as the initial value for the minimisation algorithm. Defaults to 1. See `coords.aniso` for further details on anisotropy correction.

cov.model

a string specifying the model for the correlation function. For further details see documentation for `cov.spatial`. Reads values from a variomodel object passed to `ini.cov.pars` if any, otherwise defaults to the exponential model.

realisations

optional. Logical or a vector indicating the number of replication for each datum. For further information see DETAILS below and documentation for `as.geodata`.

lik.method

(formely `method.lik`) options are "ML" for maximum likelihood and "REML" for restricted maximum likelihood. Defaults to "ML".

components

an $n \times 3$ data-frame with fitted values for the three model components: trend, spatial and residuals. See the section DETAILS below for the model specification.

nospatial

logical. If TRUE parameter estimates for the model without spatial component are included in the output.

limits

values defining lower and upper limits for the model parameters used in the numerical minimisation. The auxiliary function `pars.limits` is called to set the limits. See also Limits in DETAILS below.

print.pars

logical. If TRUE the parameters and the value of the negative log-likelihood (up to a constant) are printed each time the function to be minimised is called.

messages

logical. Indicates whether status messages should be printed on the screen (or output device) while the function is running.

object

an object with output of the function `likfit`.

spatial

logical, determines whether the spatial component of the model in included in the output. The geostatistical model components are: trend, spatial and residuals. See DETAILS.
Details

This function estimates the parameters of the Gaussian random field model, specified as:

\[ Y(x) = \mu(x) + S(x) + e \]

where

- \( x \) defines a spatial location. Typically Euclidean coordinates on a plane.
- \( Y \) is the variable been observed.
- \( \mu(x) = X\beta \) is the mean component of the model (trend).
- \( S(x) \) is a stationary Gaussian process with variance \( \sigma^2 \) (partial sill) and a correlation function parametrized in its simplest form by \( \phi \) (the range parameter). Possible extra parameters for the correlation function are the smoothness parameter \( \kappa \) and the anisotropy parameters \( \phi_R \) and \( \phi_A \) (anisotropy ratio and angle, respectively).
- \( e \) is the error term with variance parameter \( \tau^2 \) (nugget variance).

The additional parameter \( \lambda \) allows for the Box-Cox transformation of the response variable. If used (i.e. if \( \lambda \neq 1 \)) \( Y(x) \) above is replaced by \( g(Y(x)) \) such that

\[ g(Y(x)) = \frac{Y^{\lambda}(x) - 1}{\lambda}. \]

Two particular cases are \( \lambda = 1 \) which indicates no transformation and \( \lambda = 0 \) indicating the log-transformation.

Numerical minimization

In general parameter estimation is performed numerically using the R function \texttt{optim} to minimise the negative log-likelihood computed by the function \texttt{negloglikNgrf}. If the nugget, anisotropy (\( \psi_A, \psi_R \)), smoothness (\( \kappa \)) and transformation (\( \lambda \)) parameters are held fixed then the numerical minimisation can be reduced to one-dimension and the function \texttt{optimize} is used instead of \texttt{optim}. In this case initial values are irrelevant.

Limits

Lower and upper limits for parameter values can be individually specified using the function \texttt{link\{parsNlimits\}}. For example, including the following in the function call:

\[
\text{limits = parsNlimits(\phi=c(0, 10), lambda=c(-2.5, 2.5))},
\]

will change the limits for the parameters \( \phi \) and \( \lambda \). Default values are used if the argument \texttt{limits} is not provided.

There are internal reparametrisation depending on the options for parameters to be estimated. For instance for the common situation when \texttt{fix.nugget=FALSE} the minimisation is performed in a reduced parameter space using \( \tau_{red}^2 = \frac{\tau^2}{\sigma^2} \). In this case values of \( \sigma^2 \) and \( \beta \) are then given by analytical expressions which are function of the two parameters remaining parameters and limits for these two parameters will be ignored.

Since parameter values are found by numerical optimization using the function \texttt{optim}, in given circumstances the algorithm may not converge to correct parameter values when called with default options and the user may need to pass extra options for the optimizer. For instance the function \texttt{optim} takes a \texttt{control} argument. The user should try different initial values and if the parameters have different orders of magnitude may need to use options to scale the parameters. Some possible workarounds in case of problems include:
• rescale your data values (dividing by a constant, say)
• rescale your coordinates (subtracting values and/or dividing by constants)
• Use the mechanism to pass control() options for the optimiser internally

**Transformation** If the fix.lambda = FALSE and nospatial = FALSE the Box-Cox parameter for the model without the spatial component is obtained numerically, with log-likelihood computed by the function boxcox.ns.

**Multiple initial values** can be specified providing a n matrix for the argument ini.cov.pars and/or providing a vector for the values of the remaining model parameters. In this case the log-likelihood is computed for all combinations of the model parameters. The parameter set which maximises the value of the log-likelihood is then used to start the minimisation algorithm.

Alternatively the argument ini.cov.pars can take an object of the class eyefit or variomodel. This allows the usage of an output of the functions eyefit, variofit or likfit be used as initial value.

The argument **realisations** allows sets of data assumed to be independent replications of the same process. Data on different realisations may or may not be co-located. For instance, data collected at different times can be pooled together in the parameter estimation assuming time independence. The argument realisations takes a vector indicating the replication number (e.g. the times). If realisations = TRUE the code looks for an element named realisations in the geodata object. The log-likelihoods are computed for each replication and added together.

**Value**

An object of the classes "likGRF" and "variomodel".

The function **summary.likGRF** is used to print a summary of the fitted model.

The object is a list with the following components:

- **cov.model** a string with the name of the correlation function.
- **nugget** value of the nugget parameter $\tau^2$. This is an estimate if fix.nugget = FALSE otherwise, a fixed value.
- **cov.pars** a vector with the estimates of the parameters $\sigma^2$ and $\phi$, respectively.
- **kappa** value of the smoothness parameter. Valid only if the correlation function is one of: "matern", "powered.exponential", "cauchy" or "gneiting.matern".
- **beta** estimate of mean parameter $\beta$. This can be a scalar or vector depending on the trend (covariates) specified in the model.
- **beta.var** estimated variance (or covariance matrix) for the mean parameter $\beta$.
- **lambda** values of the Box-Cox transformation parameter. A fixed value if fix.lambda = TRUE otherwise the estimate value.
- **aniso.pars** fixed values or estimates of the anisotropy parameters, according to the function call.
- **method.lik** estimation method used, "ML" (maximum likelihood) or "REML" (restricted maximum likelihood).
- **loglik** the value of the maximized likelihood.
- **npars** number of estimated parameters.
value of the Akaike Information Criteria, \( AIC = -2\ln(L) + 2p \) where \( L \) is the maximised likelihood and \( p \) is the number of parameters in the model.

value of the Bayesian Information Criteria, \( BIC = -2\ln(L) + p\log(n) \), where \( n \) is the number of data, \( L, p \) as for AIC above.

data-frame with all model parameters, their status (estimated or fixed) and values.

results returned by the minimisation function.

maximum distance between 2 data points. This information relevant for other functions which use outputs from likfit.

trend (covariates) matrix \( X \).

numerical value of the logarithm of the Jacobian of the transformation.

estimates for the model without the spatial component.

the function call.

reml <- likfit(s100, ini=c(0.5, 0.5), fix.nug = TRUE, lik.met = "REML")
summary(reml)
plot(variog(s100))
lines(ml)
lines(reml, lty = 2)
## End(Not run)
```
Fits the bivariate Gaussian common component geostatistical model

Description
Computes maximum likelihood estimates of the bivariate Gaussian common component geostatistical model.

Usage
likfitBGCCM(geodata1, geodata2, ini.sigmasq, ini.phi,
    cov0.model="matern", cov1.model="matern", cov2.model="matern",
    kappa0=0.5, kappa1=0.5, kappa2=0.5,
    fc.min = c("optim", "nlminb"), ...)

Arguments
geodata1 an object of the class geodata with the first variable.
geodata2 an object of the class geodata with the second variable.
ini.sigmasq optional, a vector with initial values for the variance parameters. If not provided default values are used.
ini.phi optional, a vector with initial values for the correlation range parameters. If not provided default values are used.
cov0.model, cov1.model, cov2.model covariance model for each of the processes. See cov.spatial for details.
kappa0, kappa1, kappa2 extra parameter for some covariance models.
fc.min a string indication which function should be used to minimise the negative of the log-likelihood.
... further arguments to be passed to optim or nlminb.

Value
A list with model fitting information to which the class BGCCM is assigned.
mu a 2 elements vector with mean estimates.
sigmasq a 4 elements vector with variance estimates.
phi a 3 elements vector with estimated correlation parameters values.
loglik a scalar. Maximised value of the log-likelihood.
optim results returned by optim or nlminb.
... and other information related to the model fitting.

Warning
This is a new function and still in draft format and pretty much untested.

**lines.variogram**  
*Line with a Empirical Variogram*

Description

A sample (empirical) variogram computed using the function `variog` is added to the current plot.

Usage

```r
## S3 method for class 'variogram'
lines(x, max.dist, type = "o", scaled = FALSE,
      pts.range.cex, ...)
```

Arguments

- `x`: an object of the class "variogram", typically an output from the function `variog`.
- `max.dist`: maximum distance for the x-axis. By default takes the maximum distance for which the sample variogram was computed.
- `type`: type of line for the empirical variogram. The default is "o" (dots and lines). See documentation for `lines` for further details.
- `scaled`: logical. If TRUE the variogram values are divided by the sample variance. This allows comparison between variograms of different variables.
- `pts.range.cex`: optional. A two elements vector with maximum and minimum values for the caracter expansion factor cex. If provided the point sizes in binned variogram are proportional to the number of pairs of points used to compute each bin.
- `...`: other arguments to be passed to the function `lines`.

Value

A line with the empirical variogram is added to the plot in the current graphics device. No values are returned.
lines.variogram.envelope

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

http://www.leg.ufpr.br/geoR.

See Also

variog, lines.variogram, lines.variomodel, variog.model.env, variog.mc.env, plot.grf, lines.

Description

Variogram envelopes computed by variog.model.env or variog.mc.env are added to the current variogram plot.

Usage

```r
## S3 method for class 'variogram.envelope'
lines(x, lty = 3, ...)
```

Arguments

- `x`: an object of the class "variogram.envelope", typically an output of the functions variog.model.env or variog.mc.env.
- `lty`: line type. Defaults to 3.
- `...`: arguments to be passed to the function lines.

Value

Lines defining the variogram envelope are added to the plotin the current graphics device.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

                                 model = s100.ml)
s100.mc.env <- variog.mc.env(s100, obj.variog = s100.vario)
plot(s100.vario)
lines(s100.mod.env)
lines(s100.mc.env, lwd=2)
```

---

`lines.variomodel` *Adds a Line with a Variogram Model to a Variogram Plot*

**Description**

This function adds a line with a variogram model specified by the user to a current variogram plot. The variogram is specified either by passing a list with values for the variogram elements or using each argument in the function.

**Usage**

```r
## S3 method for class 'variomodel'
lines(x, ...)
```

```r
## Default S3 method:
lines.variomodel(x, cov.model, cov.pars, nugget, kappa,
                  max.dist, scaled = FALSE, ...)
```

**Arguments**

- `x`: a list with the values for the following components: `cov.model`, `cov.pars`, `nugget`, `kappa`, `max.dist`; or a numeric vector with values for x-axis values for the variogram (distances). This argument is not required if the other arguments in the function are provided, otherwise is compulsory. If a list is provided the arguments which match the list elements are ignored.

- `cov.model`: a string with the type of the variogram function. See documentation of `cov.spatial` for further details.

- `cov.pars`: a vector or matrix with the values for the partial sill ($\sigma^2$) and range ($\phi$) parameters.

- `nugget`: a scalar with the value of the nugget ($\tau^2$) parameter.
kappa  a scalar with the value of the smoothness ($\kappa$) parameters. Only required if cov.model is one of the following: "matern", "powered.exponential", "cauchy" and "gneiting.matern"
max.dist maximum distance (x-axis) to compute and draw the line representing the variogram model. If a list is provided in x the default is the distance given by x$max.dist$. If a vector is provided in x it takes max(x).
scaled logical. If TRUE the total sill in the plot is equals to 1.
... arguments to be passed to the function curve.

Details

Adds a line with a variogram model to a plot. In conjunction with plot.variogram can be used for instance to compare sample variograms against fitted models returned by variofit and/or likfit.

Value

A line with a variogram model is added to a plot on the current graphics device. No values are returned.

Examples

# computing and ploting empirical variogram
vario <- vario(s100, max.dist = 1)
plot(vario)
# estimating parameters by weighted least squares
vario.wls <- variofit(vario, ini = c(1, .3), fix.nugget = TRUE)
# adding fitted model to the plot
lines(vario.wls)
#
# Ploting different variogram models
plot(0:1, 0:1, type="n")
lines.variomodel(cov.model = "exp", cov.pars = c(.7, .25), nug = .3, max.dist = 1)
# an alternative way to do this is:
my.model <- list(cov.model = "exp", cov.pars = c(.7, .25), nugget = .3,
max.dist = 1)
Description

This function adds to the graphics device a line with the theoretical (true) variogram used when generating simulations with the function `grf`.

Usage

```r
## S3 method for class 'grf'
lines.variogram(x, max.dist, n = 100, ...)
```

Arguments

- `x`: an object from the class `grf` typically an output of the function `grf`.
- `max.dist`: maximum distance to compute and plot the true variogram. Defaults to the maximum distance between two data locations.
- `n`: number of points used to compute and draw the variogram line.
- `...`: further arguments to be passed to the function `curve`.

Value

A line with the true variogram model is added to the current plot on the graphics device. No values are returned.

---

lines.variogram.krig.bayes

*Adds a Bayesian Estimate of the Variogram to a Plot*

Description

Adds a Bayesian estimate of the variogram model to a plot typically with an empirical variogram. The estimate is a chosen summary (mean, mode or mean) of the posterior distribution returned by the function `krige.bayes`.

Usage

```r
## S3 method for class 'krige.bayes'
lines.variogram(x, summary.posterior, max.dist, uvec,
                posterior = c("variogram", "parameters"), ...)
```

Arguments

- `x` an object of the class `krige.bayes`, typically an output of the function `krige.bayes`.
- `summary.posterior` specify which summary of the posterior distribution should be used as the parameter estimate. Options are "mean", "median" or "mode". See DETAILS below.
- `max.dist` numerical, the maximum distance for the x-axis.
- `uvec` a numerical vector with support points to compute the variogram values. Only used if `posterior = "variogram"`. Defaults to `seq(0, max.dist, length = 51)`.
- `posterior` indicates whether the the variogram line is based on the posterior of the variogram function (default) or the posterior of the model parameters.
- `...` arguments passed to the functions `lines` or `curve`.

Details

The function `krige.bayes` returns samples from the posterior distribution of the parameters \((\sigma^2, \phi, \tau^2_{rel})\). This function allows for two basic options to draw a line with a summary of the variogram function.

1. "variogram": for each sample of the parameters the variogram function is computed at the support points defined in the argument `uvec`. Then a function provided by the user in the argument `summary.posterior` is used to compute a summary of the values obtained at each support point.
2. "parameters": in this case summaries of the posterior distribution of the model parameters as "plugged-in" in the variogram function. One of the options "mode" (default) ,"median" or "mean" can be provided in the argument summary.posterior. The option mode, uses the mode of $(\phi, \tau^2_{rel})$ and the mode of of $\sigma^2$ conditional on the modes of the former parameters. For the options mean and median these summaries are computed from the samples of the posterior.

Value

A line with the estimated variogram plot is added to the plot in the current graphics device. No values are returned.

lines.variogram.likGRF

---

Adds a Variogram Line to a Variogram Plot

Description

This function adds a fitted variogram based on the estimates of the model parameters returned by the function likfit to a current variogram plot.

Usage

```r
## S3 method for class 'likGRF'
lines.variogram(x, max.dist, scaled = FALSE, ...)
```
**Arguments**

- **x**
  an object of the class `likGRF` which is a list containing information about the fitted model parameters, typically an output of the function `likfit`.

- **max.dist**
  maximum distance (x-axis) to compute and draw the line representing the variogram model. The default is the distance given by `obj$max.dist`.

- **scaled**
  logical. If TRUE the total sill in the plot is equals to 1.

- **...**
  arguments to be passed to the function `curve`.

**Details**

Adds variogram model(s) to a plot. In conjunction with `plot.variogram` can be used to compare sample variograms against fitted models returned by `likfit`.

**Value**

A line with a variogram model is added to a plot on the current graphics device. No values are returned.

# adds fitted model to the plot
lines(vario.ml)
```
lines.variogram.variofit

Add a Line with a Fitted Variogram Model to a Variogram Plot

Description
This function adds a line with the variogram model fitted by the function variofit to a current variogram plot.

Usage

```r
## S3 method for class 'variofit'
lines.variogram(x, max.dist, scaled = FALSE, ...)
```

Arguments

- `x`: an object of the class variofit which is a list containing information about the fitted model parameters, typically an output of the function variofit.
- `max.dist`: maximum distance (x-axis) to compute and draw the line representing the variogram model. The default is the distance given by `x$max.dist`.
- `scaled`: logical. If TRUE the total sill in the plot is set to 1.
- `...`: arguments to be passed to the function curve.

Details

Adds fitted variogram model to a plot. In conjunction with plot.variogram can be used to compare empirical variograms against fitted models returned by variofit.

Value

A line with a variogram model is added to a plot on the current graphics device. No values are returned.

locations.inside Select prediction locations inside borders

Description

Selects the prediction locations located inside a polygon defining borders of a region where prediction is aimed. Typically internally called by geoR functions krige.bayes, krige.conv, ksline.

Usage

locations.inside(locations, borders, as.is = TRUE, ...)

Arguments

locations a two columns matrix or data frame with coordinates of the prediction locations.
borders a two column matrix or data-frame with coordinates of a polygon defining the borders of the region.
as.is logical defining if the returned object of the same type (list, data-frame or matrix) as the provided in locations. If FALSE the function returns a matrix.

Value

A two columns matrix, data-frame or a list with 2 elements with coordinates of points inside the borders.

See Also

over.coordinates, SpatialPoints.

Examples

gr <- pred_grid(parana$borders, by=20)
plot(gr, asp=1, pch="*")
polygon(parana$borders)
gr.in <- locations.inside(gr, parana$borders)
points(gr.in, col=2, pch="*")
loglik.GRF  
*Log-Likelihood for a Gaussian Random Field*

**Description**

This function computes the value of the log-likelihood for a Gaussian random field.

**Usage**

```r
call <- loglik.GRF(geodata, coords = geodata$coords, data = geodata$data, 
                  obj.model = NULL, cov.model = "exp", cov.pars, nugget = 0, 
                  kappa = 0.5, lambda = 1, psiR = 1, psiA = 0, 
                  trend = "cte", method.lik = "ML", compute.dists = TRUE, 
                  realisations = NULL)
```

**Arguments**

- **geodata**
  - A list containing elements `coords` and `data` as described next. Typically an object of the class "geodata" - a `geoR` data-set. If not provided the arguments `coords` and `data` must be provided instead.

- **coords**
  - An `n` × `2` matrix, each row containing Euclidean coordinates of the `n` data locations. By default it takes the element `coords` of the argument `geodata`.

- **data**
  - A vector with data values. By default it takes the element `data` of the argument `geodata`.

- **obj.model**
  - A object of the class `variomodel` with a fitted model. Typically an output of `likfit` or `variofit`.

- **cov.model**
  - A string specifying the model for the correlation function. For further details see documentation for `cov.spatial`.

- **cov.pars**
  - A vector with 2 elements with values of the covariance parameters $\sigma^2$ (partial sill) and $\phi$ (range parameter).

- **nugget**
  - Value of the nugget parameter. Defaults to 0.

- **kappa**
  - Value of the smoothness parameter. Defaults to 0.5.

- **lambda**
  - Value of the Box-Cox tranformation parameter. Defaults to 1.

- **psiR**
  - Value of the anisotropy ratio parameter. Defaults to 1, corresponding to isotropy.

- **psiA**
  - Value (in radians) of the anisotropy rotation parameter. Defaults to zero.

- **trend**
  - Specifies the mean part of the model. The options are: "cte" (constant mean), "1st" (a first order polynomial on the coordinates), "2nd" (a second order polynominal on the coordinates), or a formula of the type "X" where `X` is a matrix with the covariates (external trend). Defaults to "cte".

- **method.lik**
  - Options are "ML" for likelihood and "REML" for restricted likelihood. Defaults to "ML".

- **compute.dists**
  - For internal use with other function. Don’t change the default unless you know what you are doing.

- **realisations**
  - Optional. A vector indicating replication number for each data. For more details see `as.geodata`.

Details

The expression log-likelihood is:

\[ l(\theta) = -\frac{n}{2} \log(2\pi) - \frac{1}{2} \log |\Sigma| - \frac{1}{2} (y - F\beta)'\Sigma^{-1}(y - F\beta), \]

where \( n \) is the size of the data vector \( y \), \( \beta \) is the mean (vector) parameter with dimension \( p \), \( \Sigma \) is the covariance matrix and \( F \) is the matrix with the values of the covariates (a vector of 1’s if the mean is constant).

The expression restricted log-likelihood is:

\[ rl(\theta) = -\frac{n - p}{2} \log(2\pi) + \frac{1}{2} \log |F'F| - \frac{1}{2} \log |\Sigma| - \frac{1}{2} \log |F'\Sigma F| - \frac{1}{2} (y - F\beta)'\Sigma^{-1}(y - F\beta). \]

Value

The numerical value of the log-likelihood.

Computer Values of the Matern Correlation Function

Description

This function computes values of the Matérn correlation function for given distances and parameters.

Usage

```
matern(u, phi, kappa)
```

Arguments

- `u`: a vector, matrix or array with values of the distances between pairs of data locations.
- `phi`: value of the range parameter $\phi$.
- `kappa`: value of the smoothness parameter $\kappa$.

Details

The Matérn model is defined as:

$$
\rho(u; \phi, \kappa) = \left\{2^{\kappa-1} \Gamma(\kappa)\right\}^{-1} (u/\phi)^{\kappa} K_\kappa(u/\phi)
$$

where $\phi$ and $\kappa$ are parameters and $K_\kappa(\cdot)$ denotes the modified Bessel function of the third kind of order $\kappa$. The family is valid for $\phi > 0$ and $\kappa > 0$.

Value

A vector matrix or array, according to the argument `u`, with the values of the Matérn correlation function for the given distances.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

   xlab = "distance", ylab = expression(gamma(h)), lty = 2,
   main = "models with equivalent \"practical\" range")
curve(matern(x, phi = 0.188, kappa = 1), from = 0, to = 1, add = TRUE)
curve(matern(x, phi = 0.14, kappa = 2), from = 0, to = 1,
   add = TRUE, lwd = 2, lty = 2)
curve(matern(x, phi = 0.117, kappa = 2), from = 0, to = 1,
   add = TRUE, lwd = 2)
legend("topright", expression(list(kappa == 0.5, phi == 0.25),
   list(kappa == 1, phi == 0.188), list(kappa == 2, phi == 0.14),
   list(kappa == 3, phi == 0.117)), lty = c(2, 1, 2, 1), lwd = c(1, 1, 2, 2))
```

names.geodata

Lists names of the key elements of a geodata object

Description

Produces a list with the names of the main elements of geodata object: coords, data, units.m, covariate and realisation. Can be useful to list names before using `subset.geodata`.

Usage

```r
## S3 method for class 'geodata'
names(x)
```

Arguments

- `x` an object of the class geodata.
Value

A list with

- **coords**: names of the coordinates in the geodata object.
- **data**: name(s) of the data elements in the geodata object.
- **units.m**: returns the string `units.m`.
- **covariates**: return the covariate(s) name(s) if present in the geodata object.
- **realisations**: returns the string `units.m` if present in the geodata object.
- **other**: other elements in the geodata object.

See Also

`names`, `subset.geodata`, `as.geodata`.

Examples

`names(ca20)`

---

**nearloc**  
*Near location to a point*

Description

For a given set of points and locations identified by 2D coordinates this function finds the nearest location of each point.

Usage

`nearloc(points, locations, positions = FALSE)`

Arguments

- **points**: a matrix, data-frame or list with the 2D coordinates of a set of points for which you want to find the nearest location.
- **locations**: a matrix, data-frame or list with the 2D coordinates of a set of locations.
- **positions**: logical defining what to be returned. If TRUE the function returns the positions of the locations, otherwise the coordinates of the locations. Defaults to FALSE.

Value

If `positions = FALSE` the function returns a matrix, data-frame or list of the same type and size as the object provided in the argument `points` with the coordinates of the nearest locations.

If `positions = FALSE` the function returns a vector with the position of the nearest points in the locations object.

plot(gr, asp=1)
pts <- matrix(runif(10), nc=2)
points(pts, pch=19)
near <- nearloc(points=pts, locations=gr)
points(near, pch=19, col=2)
rownames(near)
nearloc(points=pts, locations=gr, pos=TRUE)
```

output.control

Defines output options for prediction functions

Description

Auxiliary function defining output options for `krige.bayes` and `krige.conv`.

Usage

```r
output.control(n.posterior, n.predictive, moments, n.back.moments, 
simulations.predictive, mean.var, quantile, 
threshold, sim.means, sim.vars, signal, messages)
```

Arguments

- **n.posterior**: number of samples to be taken from the posterior distribution. Defaults to 1000.
- **n.predictive**: number of samples to be taken from the predictive distribution. Default equals to `n.posterior`.
- **moments**: logical. Indicates whether the moments of the predictive distribution are returned. If `lambda = 1` there is no transformation/back-transformation. If `lambda = 0` or `lambda = 0.5` the moments are back-transformed by analytical expressions. For other cases the back-transformation is done by simulation. Defaults to TRUE.
- **n.back.moments**: number of sample to back-transform moments by simulation. Defaults to 1000.
output.control

simulations.predictive
logical. Defines whether to draw simulations from the predictive distribution. Only considered if prediction locations are provided in the argument locations of the main functions. Defaults to FALSE but changed to TRUE if an integer greater than zero is provided in the argument n.predictive and/or simulations are required in order to compute quantities required by other arguments such as threshold, quantiles and some values of the transformation parameter.

mean.var
logical (optional). Indicates whether mean and variances of the simulations of the predictive distributions are computed and returned.

quantile
a (optional) numeric vector. If provided indicates whether quantiles of the simulations from the predictive distribution are computed and returned. If a vector with numbers in the interval [0, 1] is provided, the output includes the object quantiles, which contains values of corresponding estimated quantiles. For example, if quantile = c(0.25, 0.50, 0.75) the function returns the quantiles of the predictive distributions at each of the prediction locations. If quantile = TRUE default values c(0.025, 0.5, 0.975) are assumed. A measure of uncertainty of the predictions, an alternative to the kriging standard error, computed by (quantile0.975 − quantile0.025)/4. Only used if prediction locations are provided in the argument locations.

threshold
Optional. A numerical vector. If one or more values are provided, an object named probabilities is included in the output. This object contains, for each prediction location, the probability that the variable is less than or equal than the threshold provided by the user. Defaults to FALSE.

sim.means
logical (optional). Indicates whether mean of each of the conditional simulations of the predictive distribution should be computed and returned. Defaults to TRUE, if simulations from the predictive are required.

sim.vars
logical (optional). Indicates whether variance of each of the conditional simulations of the predictive distribution should be computed and returned. Defaults to FALSE.

signal
logical indicating whether the signal or the variable is to be predicted. Different defaults are set internally by functions calling output.control. See DETAILS below.

messages
logical. Indicates whether or not status messages are printed on the output device while the function is running. Defaults to TRUE.

Details

SIGNAL
This function is typically called by the geoR's prediction functions krig.e.bayes and krig.e.conv defining the output.

By default, krig.e.bayes sets signal = TRUE and krig.e.conv sets signal = FALSE.

The underlying model

\[ Y(x) = \mu + S(x) + \epsilon \]

assumes that observations \( Y(x) \) are noisy versions of a signal \( S(x) \) and \( Var(\epsilon) = \tau^2 \) is the nugget variance.
If \( \tau^2 = 0 \) the \( Y \) and \( S \) are indistiguishable.

If \( \tau^2 > 0 \) and regarded as measurement error, the option signal defines whether the \( S \) (signal = TRUE) or the variable \( Y \) (signal = FALSE) is to be predicted.
For the latter the predictions will "honor" the data, i.e. predicted values will coincide with the data, at data locations.
For unsampled locations and untransformed data, the predicted values equals data regardless signal = TRUE or FALSE, however predictions variances will differ.
The function kriges.conv has an argument micro.scale. If \( micro.scale > 0 \) the error term is divided as \( \epsilon = \epsilon_{ms} + \epsilon_{me} \) and the nugget variance is divided into two terms: micro-scale variance and measurement error.
If signal = TRUE the term \( \epsilon_{ms} \) is regarded as part of the signal and consequently the micro-scale variance is added to the prediction variance.
If signal = FALSE the total error variance \( \tau^2 \) is added to the prediction variance.

Value

A list with processed arguments to be passed to the main function.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

The prediction functions kriges.bayes and kriges.conv.

parana

Rainfall Data from Parana State, Brasil

Description

This data-set was used by Diggle and Ribeiro (2001) to illustrate the methods discussed in the paper. The data reported analysis was carried out using the package geoR.
The data refers to average rainfall over different years for the period May-June (dry-season). It was collected at 143 recording stations throughout Paraná State, Brasil.

Usage

data(parana)
Format

The object parana of the class geodata, which is a list containing the following components:

- `coords` a matrix with the coordinates of the recording stations.
- `data` a vector with the average recorded rainfall for the May-June period.
- `borders` a matrix with the coordinates defining the borders of Paraná state.
- `loci.paper` a matrix with the coordinates of the four prediction locations discussed in the paper.

Source

The data were collected at several recording stations at Paraná State, Brasil, belonging to the following companies: COPEL, IAPAR, DNAEE, SUREHMA and INEMET.

The data base was organized by Laura Regina Bernardes Kiihl (IAPAR, Instituto Agronômico do Paraná, Londrina, Brasil) and the fraction of the data included in this data-set was provided by Jacinta Loudovico Zamboti (Universidade Estadual de Londrina, Brasil). The coordinates of the borders of Paraná State were provided by João Henrique Caviglione (IAPAR).

References

Examples

```r
summary(parana)
plot(parana, bor=borders)
```

Description

The functions `likfit` and `variofit` in the package `geoR`.

Usage

```r
pars.limits(phi = c(lower = 0, upper = +Inf),
            sigmasq = c(lower = 0, upper = +Inf),
            nugget.rel = c(lower = 0, upper = +Inf),
            kappa = c(lower = 0, upper = +Inf),
            kappa2 = c(lower = 0, upper = +Inf),
            lambda = c(lower = -3, upper = 3),
            psiR = c(lower = 1, upper = +Inf),
            psiA = c(lower = 0, upper = 2 * pi),
            tausq.rel = nugget.rel)
```
Arguments

- **phi**: a two elements vector with limits for the parameter phi. Defaults to [0, +Inf]
- **sigmasq**: idem for sigmasq. Defaults to [0, +Inf]
- **nugget.rel**: idem for nugget.rel. Defaults to [0, +Inf]
- **kappa,kappa2**: idem. Defaults to [0, +Inf]
- **lambda**: idem for lambda. Defaults to [-3, +3]. Only used in likfit.
- **psiR**: idem for psiR. Defaults to [1, +Inf]. Only used in likfit.
- **psiA**: idem for psiA. Defaults to [0, 2 pi]. Only used in likfit.
- **tausq.rel**: idem for tausq.rel. Defaults to [0, +Inf]

Details

Lower and upper limits for parameter values can be individually specified. For example, including the following in the function call in likfit or variofit:
```r
limits = pars.limits(phi=c(0, 10), lambda=c(-2.5, 2.5)),
```
will change the limits for the parameters φ and λ. Default values are used if the argument limits is not provided.

Value

A list of a 2 elements vector with limits for each parameters

See Also

likfit, variofit

Examples

```r
pars.limits(phi=c(0, 10))
pars.limits(phi=c(0, 10), sigmasq=c(0, 100))
```

Description

This function produces a 2 × 2 display with the following plots: the first indicates the spatial locations assign different colors to data in different quartiles, the next two shows data against the X and Y coordinates and the last is an histogram of the data values or optionally, a 3-D plot with spatial locations and associated data values.
Usage

```r
## S3 method for class 'geodata'
plot(x, coords=x$coords, data = x$data,
     borders, trend="cte", lambda = 1, col.data = 1,
     weights.divide = "units.m", lowess = FALSE, scatter3d = FALSE,
     density = TRUE, rug = TRUE, qt.col, ...)
```

Arguments

- `x` a list containing elements `coords` and `data` described next. Typically an object of the class "geodata" - a `geoR` data-set. If not provided the arguments `coords` and `data` must be provided instead.
- `coords` an $n \times 2$ matrix containing in each row Euclidean coordinates of the $n$ data locations. By default it takes the element `coords` of the argument `geodata`.
- `data` a vector with data values. By default it takes the element `data` of the argument `geodata`.
- `borders` If an $n \times 2$ matrix or data-frame with the borders of the area is provided, the borders are included in the first plot. By default it searches for a element named "borders" in the geodata object.
- `trend` specifies the mean part of the model. The options are: "cte" (constant mean - default option), "1st" (a first order polynomial on the coordinates), "2nd" (a second order polynomial on the coordinates), or a formula of the type ~X where X is a matrix with the covariates (external trend). If provided the trend is "removed" using the function `lm` and the residuals are plotted.
- `lambda` value of the Box-Cox transformation parameter. Two particular cases are $\lambda = 1$ which corresponds to no transformation and $\lambda = 0$ corresponding to the log-transformation.
- `col.data` indicates the column number for the data to be plotted. Only valid if more than one data-set is available i.e., if the argument `data` is a matrix.
- `weights.divide` if a vector of weights with the same length as the data is provided each data is divided by the corresponding element in this vector. Defaults divides the data by the element `units.m` in the data object, if present, otherwise no action is taken and original data is used. The usage of `units.m` is common for data objects to be analysed using the package `geoRglm`.
- `lowess` logical. Indicates whether the function `lowess` should be used in the plots of the data against the coordinates.
- `scatter3d` logical. If TRUE the last plot is produced by `scatterplot3d` showing a 3d plot with data locations and corresponding values.
- `density` logical. If TRUE (default) a line with density estimation is added to the histogram.
- `rug` logical. If TRUE a rug plot is added to the histogram.
- `qt.col` colors for the quartiles in the first plot. If missing defaults to blue, green, yellow and red.
- `...` further arguments to be passed to the function `hist` or `scatterplot3d`. 
plot.grf

Value

A plot is produced on the graphics device. No values are returned.

plot(s100)
plot(s100, scatter3d=TRUE)
plot(s100, qt.col=1)

plot(ca20, bor=borders)  # original data
plot(ca20, trend="altitude+area")  # residuals from an external trend
plot(ca20, trend="1st")  # residuals from a polynomial trend

plot(sic.100, bor=sic.borders)  # original data
plot(sic.100, bor=sic.borders, lambda=0)  # logarithm of the data
```

---

**plot.grf**

*Plots Variograms for Simulated Data*

Description

This function plots variograms for simulated geostatistical data generated by the function `grf`.

Usage

```r
## S3 method for class 'grf'
plot(x, model.line = TRUE, plot.locations = FALSE, ...)
```
Arguments

- **x**: an object of the class `grf`, typically an output of the function `grf`.
- **model.line**: logical. If `TRUE` the true variogram model is added to the plot with the sample variogram(s).
- **plot.locations**: logical. If `TRUE` a plot with data locations is also shown.
- **...**: further arguments to be passed to the functions `variog` and `plot`.

Value

A plot with the empirical variogram(s) is produced on the output device. No values are returned.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information on the package `geoR` can be found at:
http://www.leg.ufpr.br/geoR.

See Also

`grf` for simulation of Gaussian random fields, `plot.variogram` for plotting empirical variogram, `variog` for computation of empirical variograms and `plot` for the generic plotting function.

Examples

```r
op <- par(no.readonly = TRUE)
par(mfrow=c(2,1))
sim1 <- grf(100, cov.pars=c(10, .25))
# generates simulated data
plot(sim1, plot.locations = TRUE)
# plots the locations and the sample true variogram model
#
par(mfrow=c(1,1))
sim2 <- grf(100, cov.pars=c(10, .25), nsim=10)
# generates 10 simulated data
plot(sim1)
# plots sample variograms for all simulations with the true model
par(op)
```
Description

Produces plots the priors and posteriors distributions for the parameters phi and tausq.rel based on results returned by `krige.bayes`.

Usage

```r
## S3 method for class 'krige.bayes'
plot(x, phi.dist = TRUE, tausq.rel.dist = TRUE, add = FALSE,
     type=c("bars", "h", "l", "b", "o", "p"), thin, ...)
```

Arguments

- `x`: an object of the class `krige.bayes`, with an output of the functions `krige.bayes`.
- `phi.dist`: logical indicating whether or not plot the distributions for this parameter.
- `tausq.rel.dist`: logical indicating whether or not plot the distributions for this parameter.
- `add`: logical. If TRUE plots is added to current one.
- `type`: indicates the type of plot. Option "bars" uses the function `barplot` and the others uses `matplot`.
- `thin`: a numerical vector defining the thinning for values of the parameters phi and tausq.rel respectively. This improves visualisation when there are many values in the discrete distribution of the parameters.
- `...`: further arguments for the plotting function.

Value

For `plot.krige.bayes` a plot is produced or added to the current graphics device. No values are returned.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

```
plot.proflik  

Plots Profile Likelihoods

Description

This function produces plots of the profile likelihoods computed by the function proflik.

Usage

```r
## S3 method for class 'proflik'
plot(x, pages = c("user", "one", "two"), uni.only, bi.only,
type.bi = c("contour", "persp"), conf.int = c(0.90, 0.95),
yaxis.lims = c("conf.int", "as.computed"),
by.col = TRUE, log.scale = FALSE, use.splines = TRUE,
par.mar.persp = c(0, 0, 0, 0), ask = FALSE, ...)
```

Arguments

- `x`: an object of the class proflik, typically an output of the function proflik.
- `pages`: specify how the plots will be arranged in the graphics device. The default option, "user", uses the current graphical parameters. The option "one" places all the profiles in the same page and the option "two" places the univariate profiles in one page and the bivariate profiles in a second page.
- `uni.only`: only 1-D profiles are plotted even if the object contains results about the 2-D profiles.
- `bi.only`: only 2-D profile are plotted even if the object contains results about the 1-D profiles.
- `type.bi`: Type of plot for the 2-D profiles. Options are "contour" for contour plot (the default) and "persp" for perspective plot.
- `conf.int`: a vector with numbers in the interval [0, 1] specifying levels of the (approximated) confidence intervals. Defaults corresponds to the levels 90% and 95%.
- `yaxis.lims`: defines the lower limits for the y-axis in the 1-D plots. If "conf.int" the limit is determined by the level of the confidence interval (the default) otherwise will be determined by the smallest computed value.
- `by.col`: logical, If TRUE the plots are arranged by columns in a multiple graphics device.
- `log.scale`: plots the x-axis in the logarithmic scale. Defaults to FALSE.
- `use.splines`: logical. If TRUE (the default) the function spline is used to interpolate between the points computed by proflik.
- `par.mar.persp`: graphical parameters to be used with persp plots. For more details see par.
- `ask`: logical. Defines whether or not the user is prompted before each plot is produced.
- `...`: additional arguments to be passed to the functions plot, contour and/or persp.
plot.variog4

Value

Produces plots with the profile likelihoods on the current graphics device. No values are returned.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

plot.variog4  

Plot Directional Variograms

Description

This function plot directional variograms computed by the function variog. The omnidirectional variogram can be also included in the plot.

Usage

## S3 method for class 'variog'
plot(x, omnidirectional=FALSE, same.plot=TRUE, legend = TRUE, ...) 

Arguments

x  
an object of the class variog4, typically an output of the function variog. 

omnidirectional

logical. Indicates whether the omnidirectional variogram is included in the plot.

same.plot

logical. Indicates whether the directional variograms are plotted in the same or separated plots.

legend

logical indicating whether legends are automatically included in the plots.

...  
further arguments to be passed to the function plot. Typical arguments are col, lty, lwd. For same.plot = TRUE the arguments are passed to the function matplot which is used to produce the plot.
plot.variogram

Value

A plot is produced on the output device. No values returned.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information about the geoR package can be found at:
http://www.leg.ufpr.br/geoR.

See Also

variog4 for variogram calculations and matplot for multiple lines plotting.

Examples

```r
s100.v4 <- variog4(s100, max.dist=1)
# Plotting variograms for the four directions
plot(s100.v4)
# changing plot options
plot(s100.v4, lwd=2)
plot(s100.v4, lty=1, col=c("darkorange", "darkblue", "darkgreen","darkviolet"))
plot(s100.v4, lty=1, lwd=2)
# including the omnidirectional variogram
plot(s100.v4, omni=TRUE)
# variograms on different plots
plot(s100.v4, omni=TRUE, same=FALSE)
```

---

plot.variogram  

Plot Empirical Variogram

Description

Plots sample (empirical) variogram computed using the function variog.

Usage

```r
## S3 method for class 'variogram'
plot(x, max.dist, vario.col = "all", scaled = FALSE,
     var.lines = FALSE, envelope.obj = NULL,
     pts.range.cex, bin.cloud = FALSE, ...)
```
Arguments

- **x**: an object of the class "variogram", typically an output of the function `variog`.
- **max.dist**: maximum distance for the x-axis. The default is the maximum distance for which the sample variogram was computed.
- **vario.col**: only used if `obj` has information on more than one empirical variogram. The default "all" indicates that variograms of all variables should be plotted. Alternatively a numerical vector can be used to select variables.
- **scaled**: If TRUE the variogram values are divided by the sample variance. This allows comparison of variograms of variables measured in different scales.
- **var.lines**: If TRUE a horizontal line is drawn at the value of the variance of the data (if scaled = F) or at 1 (if scaled = T).
- **envelope.obj**: adds a variogram envelope computed by the function `variog.model.env` or `variog.mc.env`.
- **pts.range.cex**: optional. A two elements vector with maximum and minimum values for the character expansion factor `cex`. If provided the point sizes in binned variogram are proportional to the number of pairs of points used to compute each bin.
- **bin.cloud**: logical. If TRUE and the sample variogram was computed with the option `bin.cloud = TRUE`, box-plots of values at each bin are plotted instead of the empirical variograms.
- **...**: other arguments to be passed to the function `plot` or `matplot`.

Details

This function plots empirical variograms. Together with `lines.variogram` can be used to compare sample variograms of different variables and to compare variogram models against the empirical variogram.

It uses the function `matplot` when plotting variograms for more than one variable.

Value

Produces a plot with the sample variogram on the current graphics device. No values are returned.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>

References

Further information on the package `geoR` can be found at:
http://www.leg.ufpr.br/geoR.

See Also

`variog` for variogram calculations, `lines.variogram` and `lines.variomodel` for adding lines to the current plot, `variog.model.env` and `variog.mc.env` for variogram envelopes computation, `matplot` for multiple lines plot and `plot` for generic plot function.
Examples

```r
op <- par(no.readonly = TRUE)
sim <- grf(100, cov.pars=c(1, .2)) # simulates data
vario <- variog(sim, max.dist=1) # computes sample variogram
par(mfrow=c(2,2))
plot(vario) # the sample variogram
plot(vario, scaled = TRUE) # the scaled sample variogram
plot(vario, max.dist = 1) # limiting the maximum distance
plot(vario, pts.range = c(1,3)) # points sizes proportional to number of pairs
par(op)
```

---

**Description**

This function produces ten plots with the results produced by the cross-validation function `xvalid`.

**Usage**

```r
## S3 method for class 'xvalid'
plot(x, coords, borders = NULL, ask = TRUE,
     error = TRUE, std.error = TRUE, data.predicted = TRUE,
     pp = TRUE, map = TRUE, histogram = TRUE,
     error.predicted = TRUE, error.data = TRUE, ...)
```

**Arguments**

- `x` an object of the class "xvalid", typically an output from the function `xvalid`.
- `coords` an \( n \times 2 \) object containing coordinates of the (cross)-validation locations.
- `borders` optional. Takes a two column matrix or data-frame with coordinates of the borders. If provided the borders are included in the errors maps.
- `ask` logical. Defines whether or not the user is prompted before each plot is produced.
- `error` logical. Defines whether the plots for the errors (\( error = data - predicted \)) will be produced.
- `std.error` logical. Defines whether the plots for the standardised errors will be produced.
- `data.predicted` logical defining whether a plot of data versus predicted should be displayed. Defaults to TRUE.
- `pp` logical defining whether a \( pp \) plot should be displayed. Defaults to TRUE.
- `map` logical defining whether a map of the errors should be displayed. Defaults to TRUE.
- `histogram` logical defining whether a histogram of the errors should be displayed. Defaults to TRUE.
plot.xvalid

**error.predicted**

logical defining whether a plot of errors versus predicted should be displayed. Defaults to TRUE.

**error.data**

logical defining whether a plot of errors versus data should be displayed. Defaults to TRUE.

... other arguments to be passed to the function *plot*.

**Details**

The number of plots to be produced will depend on the input options. If the graphics device is set to just one plot (something equivalent to ‘par(mfcol=c(1,1))’) after each graphic being displayed the user will be prompt to press <return> to see the next graphic.

Alternatively the user can set the graphical parameter to have several plots in one page. With default options for the arguments the maximum number of plots (10) is produced and setting ‘par(mfcol=c(5,2))’ will display them in the same page.

The “errors” for the plots are defined as

\[ error = data - predicted \]

and the plots uses the color blue to indicate positive errors and red to indicate negative errors.

**Value**

No value returned. Plots are produced on the current graphics device.

**See Also**

*xvalid* for the cross-validation computations.

**Examples**

```r
wls <- variofit(variog(s100, max.dist = 1), ini = c(.5, .5), fix.n = TRUE)
xvl <- xvalid(s100, model = wls)
#
op <- par(no.readonly = TRUE)
par(mfcol = c(3,2))
par(mar = c(3,3,0,1))
par(mgp = c(2,1,0))
plot(xvl, error = FALSE, ask = FALSE)
plot(xvl, std.err = FALSE, ask = FALSE)
par(op)
```
Description

This function produces a plot with points indicating the data locations. Arguments can control the points sizes, patterns and colors. These can be set to be proportional to data values, ranks or quantiles. Alternatively, points can be added to the current plot.

Usage

```r
## S3 method for class 'geodata'
points(x, coords=x$coords, data=x$data, data.col = 1, borders,
       pt.divide=c("data.proportional","rank.proportional",
                  "quintiles","quartiles","deciles","equal"),
       lambda = 1, trend = "cte", abs.residuals = FALSE,
       weights.divide = "units.m", cex.min, cex.max, cex.var,
       pch.seq, col.seq, add.to.plot = FALSE,
       x.leg, y.leg = NULL, dig.leg = 2,
       round.quantiles = FALSE, permute = FALSE, ...)
```

Arguments

- `x`: a list containing elements `coords` and `data` described next. Typically an object of the class "geodata" - a geoR data-set. If not provided the arguments `coords` and `data` must be provided instead.
- `coords`: an \( n \times 2 \) matrix containing coordinates of the \( n \) data locations in each row. Defaults to `geodata$coords`.
- `data`: a vector or matrix with data values. If a matrix is provided each column is regarded as one variable or realization. Defaults to `geodata$data`.
- `data.col`: the number of the data column. Only used if data is a matrix with columns corresponding to different variables or simulations.
- `borders`: If an \( n \times 2 \) matrix or data-frame with the coordinates of the borders of the regions is provided, the borders are added to the plot. By default it searches for a element named "borders" in the geodata object.
- `pt.divide`: defines the division of the points in categories. See `DETAILS` below for the available options. Defaults to `pt.divide = "data.proportional"`.
- `trend`: specifies the mean part of the model. The options are: "cte" (constant mean - default option), "1st" (a first order polynomial on the coordinates), "2nd" (a second order polynomial on the coordinates), or a formula of the type ~\( X \) where \( X \) is a matrix with the covariates (external trend). If provided the trend is "removed" using the function `lm` and the residuals are plotted.
- `abs.residuals`: logical. If `TRUE` and the value passed to the argument `trend` is different from "cte" the point sizes are proportional to absolute values of the residuals.
lambda value of the Box-Cox transformation parameter. Two particular cases are $\lambda = 1$
which corresponds to no transformation and $\lambda = 0$ corresponding to the log-
transformation.

weights.divide if a vector of weights with the same length as the data is provided each data is
divided by the corresponding element in this vector. Defaults divides the data by
the element units.m in the data object, if present, otherwise no action is taken
and original data is used. The usage of units.m is common for data objects to
be analysed using the package geoRglm.

cex.min minimum value for the graphical parameter cex. This value defines the size of
the point corresponding the minimum of the data. Defaults to 0.5.

cex.max maximum value for the graphical parameter cex. This value defines the size of
the point corresponding the maximum of the data. If pt.divide = "equal" it
is used to set the value for the graphical parameter cex. Defaults to 1.5.

cex.var a numeric vector with the values of a variable defining the size of the points.
Particularly useful for displaying 2 variables at once.

pch.seq number(s) defining the graphical parameter pch.

col.seq number(s) defining the colors in the graphical parameter col.

add.to.plot logical. If TRUE the points are added to the current plot or image otherwise a
display is open. Defaults to FALSE.

x.leg, y.leg x and y location of the legend as documented in legend.

dig.leg the desired number of digits after the decimal point. Printing values in the legend
uses formatC with argument format = "$f$".

round.quantiles logical. Defines whether or not the values of the quantiles should be rounded.
Defaults to FALSE.

permute logical indication whether the data values should be randomly re-allocated to
the coordinates. See DETAILS below.

... further arguments to be passed to the function plot, if add.to.plot = FALSE;
or to the function points, if add.to.plot = TRUE.

Details
The points can be divided in categories and have different sizes and/or colours according to the
argument pt.divide. The options are:

"data.proportional" sizes proportional to the data values.
"rank.proportional" sizes proportional to the rank of the data.
"quintiles" five different sizes according to the quintiles of the data.
"quartiles" four different sizes according to the quartiles of the data.
"deciles" ten different sizes according to the deciles of the data.
"equal" all points with the same size.

a scalar defines a number of quantiles, the number provided defines the number of different points
sizes and colors.
**a numerical vector with quantiles and length > 1** the values in the vector will be used by the function `cut` as break points to divide the data in classes.

For cases where points have different sizes the arguments `cex.min` and `cex.max` set the minimum and the maximum point sizes. Additionally, `pch.seq` can set different patterns for the points and `col.seq` can be used to define colors. For example, different colors can be used for quartiles, quintiles and deciles while a sequence of gray tones (or a color sequence) can be used for point sizes proportional to the data or their ranks. For more details see the section **EXAMPLES**.

The argument `cex.var` allows for displaying 2 variables at once. In this case one variable defines the background colour of the points and the other defines the points size.

The argument `permute` if set to `TRUE` randomly reallocates the data in the coordinates. This may be used to contrast the spatial pattern of original data against another situation where there is no spatial dependence (when setting `permute = TRUE`). If a trend is provided the residuals (and not the original data) are permuted.

**Value**

A plot is created or points are added to the current graphics device. A list with graphical parameters used to produce the plot is returned invisibly. According to the input options, the list has some or all of the following components:

- `quantiles`: the values of the quantiles used to divide the data.
- `cex`: the values of the graphics expansion parameter `cex`.
- `col`: the values of the graphics color parameter `col`.
- `pch`: the values of the graphics pattern parameter `pch`.

               cex.var=camg[,5])
points.geodata(coords=camg[,1:2], data=camg[,3], col="gray",
               cex.var=camg[,5], pt.div="quint")

---

polygrid

### Coordinates of Points Inside a Polygon

Description

This function builds a rectangular grid and extracts points which are inside of an internal polygonal region.

Usage

polygrid(xgrid, ygrid, borders, vec.inout = FALSE, ...)

Arguments

- **xgrid**: grid values in the x-direction.
- **ygrid**: grid values in the y-direction.
- **borders**: a matrix with polygon coordinates defining the borders of the region.
- **vec.inout**: logical. If TRUE a logical vector is included in the output indicating whether each point of the grid is inside the polygon. Defaults to FALSE.
- **...**: currently not used (kept for back compatibility).

Details

The function works as follows: First it creates a grid using the R function `expand.grid` and then it uses the geoR' internal function `geoR_inout()` which wraps usage of `SpatialPoints` and `over` from the package `sp` to extract the points of the grid which are inside the polygon.

Within the package `geoR` this function is typically used to select points in a non-rectangular region to perform spatial prediction using `krige.bayes`, `krige.conv` or `ksline`. It is also useful to produce image or perspective plots of the prediction results.
practicalRange

Value

A list with components:

- xypoly: an $n \times 2$ matrix with the coordinates of the points inside the polygon.
- vec.inout: logical, a vector indicating whether each point of the rectangular grid is inside the polygon. Only returned if vec.inout = TRUE.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information on the package geoR can be found at:
http://www.leg.ufpr.br/geoR.

See Also

pred_grid, expand.grid, over, SpatialPoints.

Examples

```r
poly <- matrix(c(.2, .8, .7, .1, .2, .1, .2, .7, .7, .1), ncol=2)
plot(0:1, 0:1, type="n")
lines(poly)
poly.in <- polygrid(seq(0,1,l=11), seq(0,1,l=11), poly, vec=TRUE)
points(poly.in$xy)
```

practicalRange  Pratical range for correlation functions

Description

Computes practical ranges for the correlation functions implemented in the geoR package

Usage

```r
practicalRange(cov.model, phi, kappa = 0.5, correlation = 0.05, ...)
```

Arguments

- cov.model: correlation model as documented in cov.spatial.
- phi: correlation parameter as documented in cov.spatial.
- kappa: additional correlation parameter as documented in cov.spatial.
- correlation: correlation threshold for asymptotic models. Defaults to 0.05.
- ...: arguments to be passed to optimise.
Value

A scalar with the value of the practical range.

See Also

cov.spatial

Examples

 practicalRange("exp", phi=10)
 practicalRange("sph", phi=10)
 practicalRange("gaus", phi=10)
 practicalRange("matern", phi=10, kappa=0.5)
 practicalRange("matern", phi=10, kappa=1.5)
 practicalRange("matern", phi=10, kappa=2.5)

predict.BGCCM  Prediction for the bivariate Gaussian common component geostatistical model

Description

Performs prediction for the bivariate Gaussian common component geostatistical model

Usage

## S3 method for class 'BGCCM'
predict(object, locations, borders,
        variable.to.predict = 1, ...)

Arguments

object an object of the class BGCCMfit, which is an output of likfitBGCCM.
locations an N x 2 matrix or data-frame with the 2-D coordinates of the N prediction locations, or a list for which the first two components are used. Input is internally checked by the function check.locations.

borders optional. If missing, by default reads the element borders of the geodata object of the variable to be predicted. Ignored if set to NULL. If a two column matrix defining a polygon is provided the prediction is performed only at locations inside this polygon.

variable.to.predict scalar with options for values or 2 indicating which variable is to be predicted.

... not yet used.
pred_grid

Value

A list of the class BGCCMpred with components:

- predicted: predicted values.
- krig.var: prediction variances.

Warning

This is a new function and still in draft format and pretty much untested.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

-----

pred_grid  Generates a 2D Prediction Grid

-----

Description

This function facilitates the generation of a 2D prediction grid for geostatistical kriging.

Usage

pred_grid(coords, y.coords = NULL, ..., y.by = NULL,
          y.length.out = NULL, y.along.with = NULL)

Arguments

- coords: a list, matrix or data-frame with xy-coordinates of prediction points or a vector with x-coordinates.
- y.coords: a vector with y-coordinates. Needed if argument coords provides only x-coordinates.
- ...: arguments by or length.out to be passed to the function rep. These arguments are used for the x-coordinates and are default options for y-coordinates.
- y.by: Optional. by argument for rep to be used with the y-coordinates.
- y.length.out: Optional. length.out argument for rep to be used with the y-coordinates.
- y.along.with: Optional. along.with argument for rep to be used with the y-coordinates.
Value

An two column data-frame which is on output of `expand.grid`.

See Also

See `seq` and `expand.grid` which are used internally and `locations.inside` and `polygrid` to select points inside a border.

Examples

```r
pred_grid(c(0,1), c(0,1), by=0.25) ## create a grid in a unit square
loc0 <- pred_grid(ca20$Borders, by=20)
points(ca20, borders=borders)
points(loc0, pch="+")
points(locations.inside(loc0, ca20$border), pch="+", col=2)
```

print.BGCCM

*Prints an summary of of the output from likfitBGCCM.*

Description

Prints a short version of an object of the class BGCCM.

Usage

```r
## S3 method for class 'BGCCM'
print(x, ...)
```

Arguments

- `x` an object of the class BGCCM.
- `...` arguments to be passed to `format`.

See Also

`format` for options to format the output.
proflik

Computes Profile Likelihoods

Description
Computes profile likelihoods for model parameters previously estimated using the function likfit.

Usage
proflik(obj.likfit, geodata, coords = geodata$coords,
     data = geodata$data, sill.values, range.values,
     nugget.values, nugget.rel.values, lambda.values,
     sill.range.values = TRUE, sill.nugget.values = TRUE,
     range.nugget.values = TRUE, sill.nugget.rel.values = FALSE,
     range.lambda.values = FALSE, sill.lambda.values = FALSE,
     range.lambda.values = TRUE, nugget.lambda.values = FALSE,
     nugget.rellambda.values = FALSE,
     uni.only = TRUE, bi.only = FALSE, messages, ...)

Arguments

obj.likfit an object of the class likfit, typically an output of the function likfit.
geodata a list containing elements coords and data described next. Typically an object of the class "geodata" - a geoR data-set. If not provided the arguments coords and data must be provided instead.
coords an \( n \times 2 \) matrix containing in each row Euclidean coordinates of the \( n \) data locations. By default it takes the element coords of the argument geodata.
data a vector with data values. By default it takes the element data of the argument geodata.
sill.values set of values of the partial sill parameter \( \sigma^2 \) for which the profile likelihood will be computed.
range.values set of values of the range parameter \( \phi \) for which the profile likelihood will be computed.
nugget.values set of values of the nugget parameter \( \tau^2 \) for which the profile likelihood will be computed. Only used if the model was fitted using the function likfit with the option fix.nugget = FALSE.
nugget.rel.values set of values of the relative nugget parameter \( \tau^2_R \) for which the profile likelihood will be computed. Only used if the model was fitted using the function likfit with the option fix.nugget = FALSE.
lambda.values set of values of the Box-Cox transformation parameter \( \lambda \) for which the profile likelihood will be computed. Only to be used if the model was fitted using the function likfit with the option fix.lambda = FALSE.
sillrange.values
   logical indicating whether or not the 2-D profile likelihood should be computed.
   Only valid if uni.only = FALSE.

sillnugget.values
   as above.
rangennugget.values
   as above.
sillnugget.rel.values
   as above.
rangennugget.rel.values
   as above.
silllambda.values
   as above.
rangelambda.values
   as above.
nuggetlambda.values
   as above.
nugget.rellambda.values
   as above.
uni.only
   as above.
bi.only
   as above.
messages
   logical. Indicates whether status messages should be printed on the screen (i.e.
   current output device) while the function is running.

... additional parameters to be passed to the minimization function.

Details

The functions `proflik.*` are auxiliary functions used to compute the profile likelihoods. These
functions are internally called by the minimization functions when estimating the model parameters.

Value

An object of the class "proflik" which is a list. Each element contains values of a parameter (or
a pair of parameters for 2-D profiles) and the corresponding value of the profile likelihood. The
components of the output will vary according to the input options.

Note

1. Profile likelihoods for Gaussian Random Fields are usually uni-modal. Unusual or jagged
   shapes can be due to the lack of the convergence in the numerical minimization for particular
   values of the parameter(s). If this is the case it might be necessary to pass control arguments
to the minimization functions using the argument .... It’s also advisable to try the different
   options for the minimisation.function argument. See documentation of the functions
   optim and/or nlm for further details.

2. 2-D profiles can be computed by setting the argument uni.only = FALSE. However, before
   computing 2-D profiles be sure they are really necessary. Their computation can be time de-
   manding since it is performed on a grid determined by the cross-product of the values defining
   the 1-D profiles.
3. There is no "default strategy" to find reasonable values for the x-axis. They must be found in a "try-and-error" exercise. It's recommended to use short sequences in the initial attempts. The EXAMPLE section below illustrates this.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information on the package geoR can be found at:
http://www.leg.ufpr.br/geoR.

See Also

plot.proflik for graphical output, likfit for the parameter estimation, optim and nlm for further details about the minimization functions.

Examples

```r
op <- par(no.readonly=TRUE)
ml <- likfit(s100, ini=c(.5, .5), fix.nug=TRUE)
## a first attempt to find reasonable values for the x-axis:
prof <- proflik(ml, s100, sill.values=seq(0.5, 1.5, l=4),
   range.val=seq(0.1, .5, l=4))
par(mfrow=c(1,2))
plot(prof)
## a nicer setting
## Not run:
prof <- proflik(ml, s100, sill.values=seq(0.45, 2, l=11),
   range.val=seq(0.1, .55, l=11))
plot(prof)
## to include 2-D profiles use:
## (commented because this is time demanding)
#prof <- proflik(ml, s100, sill.values=seq(0.45, 2, l=11),
#   range.val=seq(0.1, .55, l=11), uni.only=FALSE)
#par(mfrow=c(2,2))
#plot(prof, nlevels=16)

## End(Not run)
par(op)
```

---

**read.geodata**

Reads and Converts Data to geoR Format

**Description**

Reads data from a ASCII file and converts it to an object of the class geodata, the standard data format for the geoR package.
Usage

read.geodata(file, header = FALSE, coords.col = 1:2, data.col = 3, data.names = NULL, covar.col = NULL, covar.names = "header", units.m.col = NULL, realisations = NULL, na.action = c("ifany", "ifdata", "ifcovar", "none"), rep.data.action, rep.covar.action, rep.units.action, ...)

Arguments

file a string with the name of the ASCII file.
header logical. Indicates whether the variables names should be read from the first line of the input file.
coords.col a vector with the numbers of the columns containing the coordinates.
data.col a scalar or vector with the number of the column(s) containing the data.
data.names a string or vector of strings with names for the data columns. Only valid if there is more than one column of data. By default the names in the original object are used.
covar.col optional. A scalar or vector with the number of the column(s) with the values of the covariate(s).
covar.names optional. A vector with the names of the the covariates. By default the names in the original object are used.
units.m.col optional. A scalar with the column number corresponding to the offset variable. Alternatively can be a character vector with the name of the offset. This option is particularly relevant when using the package geoRglm.
realisations optional. A vector indicating the replication number. For more details see documentation for as.geodata.
na.action a string. Defines action to be taken in the presence of NA’s. For more details see documentation for as.geodata.
rep.data.action a string or a function. Defines action to be taken when there is more than one data at the same location. For more details see documentation for as.geodata.
rep.covar.action a string or a function. Defines action to be taken when there is more than one covariate at the same location. For more details see documentation for as.geodata.
rep.units.action a string or a function. Defines action to be taken on the element units.m, if present when there is more than one data at the same location. The default option is the same value set for rep.data.action.
...

Details

The function read.table is used to read the data from the ASCII file and then as.geodata is used to convert to an object of the class geodata.
Value

An object of the class `geodata`. See documentation for the function `as.geodata` for further details.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

---

s100 and s121  Simulated Data-Sets which Illustrate the Usage of the Package geoR

Description

These two simulated data sets are the ones used in the Technical Report which describes the package `geoR` (see reference below). These data-sets are used in several examples throughout the package documentation.

Usage

```r
data(s100)
data(s121)
```

Format

Two objects of the class `geodata`. Both are lists with the following components:

- `coords` the coordinates of data locations.
- `data` the simulated data. Notice that for `s121` this a `121 × 10` matrix with 10 simulations.
- `cov.model` the correlation model.
- `nugget` the values of the nugget parameter.
- `cov.pars` the covariance parameters.
- `kappa` the value of the parameter `kappa`.
- `lambda` the value of the parameter `lambda`. 
References

Further information on the package geoR can be found at: http://www.leg.ufpr.br/geoR.

Examples

plot(s100)
plot(s121, type="l")

s256i Simulated Data-Set which Illustrate the Usage of krige.bayes

Description

This is the simulated data-set used in the Technical Report which describes the implementation of the function krige.bayes (see reference below).

Usage

data(s256i)

Format

Two objects of the class geodata. Both are lists with the following components:

coords  the coordinates of data locations.
data  the simulated data.

References

Further information about the geoR package can be found at: http://www.leg.ufpr.br/geoR.

Examples

points(s256i, pt.div="quintiles", cex.min=1, cex.max=1)
Sample geodata

Sampling from geodata objects

Description

This function facilitates extracting samples from geodata objects.

Usage

sample.geodata(x, size, replace = FALSE, prob = NULL, coef.logCox, external)

Arguments

- **x**: an object of the class geodata.
- **size**: non-negative integer giving the number of items to choose.
- **replace**: Should sampling be with replacement?
- **prob**: A vector of probability weights for obtaining the elements of the data points being sampled.
- **coef.logCox**: optional. A scalar with the coefficient for the log-Cox process. See DETAILS below.
- **external**: numeric values of a random field to be used in the log-Cox inhomogeneous poisson process.

Details

If prob=NULL and the argument coef.logCox is provided, sampling follows a log-Cox process, i.e. the probability of each point being sampled is proportional to:

\[ \exp(bY(x)) \]

with \( b \) given by the value passed to the argument coef.logCox and \( Y(x) \) taking values passed to the argument external or, if this is missing, the element data of the geodata object. Therefore, the latter generates a preferential sampling.

Value

a list which is an object of the class geodata.

See Also

as.geodata, sample.
**Examples**

```r
par(mfrow=c(1,2))
S1 <- grf(2500, grid="reg", cov.pars=c(1, .23))
image(S1, col=gray(seq(0.9,0.1,1=100)))
y1 <- sample.geodata(S1, 80)
points(y1$coords, pch=19)
## Now a preferential sampling
y2 <- sample.geodata(S1, 80, coef=1.3)
## which is equivalent to
## y2 <- sample.geodata(S1, 80, coef=1.3)
## points(y2$coords, pch=19, col=2)
## and now a clustered (but not preferential)
S2 <- grf(2500, grid="reg", cov.pars=c(1, .23))
y3 <- sample.geodata(S1, 80, prob=exp(1.3*S2$data))
## which is equivalent to
## points(y3$coords, pch=19, col=4)
image(S2, col=gray(seq(0.9,0.1,1=100)))
points(y3$coords, pch=19, col=4)
```

---

**sample.posterior**

**Samples from the posterior distribution**

**Description**

Sample quadruples \((\beta, \sigma^2, \phi, \tau_{rel}^2)\) from the posterior distribution returned by `krige.bayes`.

**Usage**

```r
sample.posterior(n, kb.obj)
```

**Arguments**

- `n` number of samples
- `kb.obj` on object with an output of `krige.bayes`.

**Value**

A \(n \times 4\) data-frame with samples from the posterior distribution of the model parameters.

**Author(s)**

Paulo J. Ribeiro Jr. `<paulojus@leg.ufpr.br>`,
Peter J. Diggle `<p.diggle@lancaster.ac.uk>`.

**References**

Further information on the package `geoR` can be found at:

[http://www.leg.ufpr.br/geoR](http://www.leg.ufpr.br/geoR).
Sample the prior distribution

Description

Sample quadruples \((β, σ^2, φ, τ^2_{rel})\) from the prior distribution of parameters specifying a Gaussian random field. Typically the prior is specified in the same manner as when calling \texttt{krige.bayes}.

Usage

```r
sample.prior(n, kb.obj=NULL, prior=prior.control())
```

Arguments

- \(n\) number of samples
- \(kb.obj\) an object with an output of \texttt{krige.bayes}.
- \(prior\) an call to \texttt{prior.control}. Unnecessary if \(kb.obj\) is provided.

Value

A \(p + 3 \times 4\) data-frame with a sample of the prior distribution of model parameters, where \(p\) is the length of the mean parameter \(β\).

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information on the package \texttt{geoR} can be found at: \url{http://www.leg.ufpr.br/geoR}.

See Also

- \texttt{krige.bayes} and \texttt{sample.posterior}.

Examples

```r
sample.prior(50,
            prior=prior.control(bbeta.prior = "normal", beta = .5, beta.var.std=0.1,
                               sigmasq.prior="sc", sigmasq=1.2, df.sigmasq= 2,
                               phi.prior="rec", phi.discrete = seq(0.2, l=21)))
```
set.coords.lims

Sets Limits to Scale Plots

Description

This is an function typically called by functions in the package geoR to set limits for the axis when plotting spatial data.

Usage

set.coords.lims(coords, borders = coords, xlim, ylim, ...)

Arguments

- coords: an \( n \times 2 \) matrix with coordinates.
- borders: an \( n \times 2 \) matrix with coordinates.
- xlim, ylim: the ranges to be encompassed by the x and y axes.
- ...: not used, included just for internal handling.

Value

A \( 2 \times 2 \) matrix with limits for the axis.

Author(s)

Paulo J. Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

data(SIC)

Spatial Interpolation Comparison data

Description

Data from the SIC-97 project: Spatial Interpolation Comparison.

Usage

data(SIC)
Format

Four objects of the class "geodata": sic.all, sic.100, sic.367, sic.some. Each is a list with two components:

coords the coordinates of the data locations. The distance are given in kilometers.
data rainfall values. The unit is milimeters.
alitude elevation values. The unit is milimeters.

Additionally an matrix sic.borders with the borders of the country.

Source

Data from the project Spatial Interpolation Comparison 97; see https://wiki.52north.org/bin/view/A1_GEOSTATS/EventsSIC97.

soil250 Soil chemistry properties data set

Description

Several soil chemistry properties measured on a regular grid with 10x25 points spaced by 5 meters.

Usage

data(soil250)

Format

A data frame with 250 observations on the following 22 variables.

Linha x-coordinate
Coluna y-coordinate
Cota elevation
AGrossa a numeric vecto, sand portion of the sample.
soil250

Silte a numeric vector, silt portion of the sample.
Argila a numeric vector, sand portion of the sample.
pHAgua a numeric vector, soil pH at water
pHKCl a numeric vector, soil pH by KCl
Ca a numeric vector, calcium content
Mg a numeric vector, magnesium content
K a numeric vector, potassio content
Al a numeric vector, aluminium content
H a numeric vector, hidrogen content
C a numeric vector, carbon content
N a numeric vector, nitrogen content
CTC a numeric vector, catium exchange capability
S a numeric vector, enxofrar content
V a numeric vector
M a numeric vector
NC a numeric vector
CEC a numeric vector
CN a numeric vector, carbon/nitrogen relation

Details

Uniformity trial with 250 undisturbed soil samples collected at 25cm soil depth of spacing of 5 meters, resulting on a regular grid of $25 \times 10$ points.

See also the data-set wrc with other variables collected at the same points.

plot(ctc)
soja98  Soya bean production and other variables in a uniformity trial

Description

Data on soya bean production in a uniformity trial measured at plots of size 5x5 meters and other soil properties measured in points given by the data coordinates.

Usage

data(soja98)

Format

A data frame with 256 observations on the following 10 variables.

- X a numeric vector with X-coordinates of the plot centres.
- Y a numeric vector with X-coordinates of the plot centres.
- P a numeric vector, phosphorous content.
- PH a numeric vector, soil pH.
- K a numeric vector, potassium content. (Cmol/dm^3)
- MO a numeric vector, organic matter. (percentage)
- SB a numeric vector, basis saturation.
-icone a numeric vector, cone index, measuring mechanic resistence of the soil. (kg/cm^2)
- rend a numeric vector, total soya production within the plot (kg).
- prod a numeric vector, production converted to productivity by a unit of area - hectare (ton/ha).

Source

Examples

data(soja98)
plot(soja98)
require(geoR)
prod98 <- as.geodata(soja98, coords.col=1:2, data.col=)
plot(prod98, low=TRUE)
Summary statistics from predictive distributions

Description

Computes summaries based on simulations of predictive distribution returned by \texttt{krige.bayes} and \texttt{krige.conv}.

Usage

\begin{verbatim}
statistics.predictive(simuls, mean.var = TRUE, quantile, threshold, 
    sim.means, sim.vars)
\end{verbatim}

Arguments

- \texttt{simuls}: object with simulations from the predictive distribution
- \texttt{mean.var}: Logical. Indicates whether or not to compute mean and variances of the simulations at each location.
- \texttt{quantile}: defines quantile estimator. See documentation for \texttt{output.control}.
- \texttt{threshold}: defines probability estimator. See documentation for \texttt{output.control}.
- \texttt{sim.means}: Logical. Indicates whether or not to compute the mean of the conditional simulations.
- \texttt{sim.vars}: Logical. Indicates whether or not to compute the variances of the conditional simulations.

Value

A list with one or more of the following components.

- \texttt{mean}: mean at each prediction location.
- \texttt{variance}: variance at each prediction location.
- \texttt{quantiles}: quantiles, at each prediction location.
- \texttt{probabilities}: probabilities, at each prediction location, of being below the provided threshold.
- \texttt{sim.means}: vector with means of each conditional simulation.
- \texttt{sim.vars}: vector with variances of each conditional simulation.

\url{http://www.leg.ufpr.br/geoR}. 
subarea

Selects a Subarea from a Geodata Object

Description

Selects elements of a geodata object which are within a rectangular (sub)area

Usage

subarea(geodata, xlim, ylim, ...)

Arguments

geodata an object of the class geodata as defined in as.geodata.
xlim optional, a vector with selected range of the x-coordinates.
ylim optional, a vector with selected range of the y-coordinates.
... further arguments to be passed to zoom.coords.

Details

The function copies the original geodata object and selects values of $coords, $data, $borders, $covariate and $units.m which lies within the selected sub-area. Remaining components of the geodata objects are untouched.

If xlim and/or ylim are not provided the function prompts the user to click 2 points defining an rectangle defining the subarea on a existing plot.

Value

Returns an geodata object, subsetting of the original one provided.

Author(s)

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>, Peter J. Diggle <p.diggle@lancaster.ac.uk>.

foo2
plot(1:10, 1:10, type="n")
subset.geodata

Method for subsetting geodata objects

**Description**

Subsets a object of the class geodata by transforming it to a data-frame, using subset and back transforming to a geodata object.
Usage

```r
## S3 method for class 'geodata'
subset(x, ..., other = TRUE)
```

Arguments

- `x`: an object of the class `geodata`.
- `...`: arguments to be passed to `subset.data.frame`.
- `other`: logical. If `TRUE` non-standard `geodata` elements of the original `geodata` object are copied to the resulting object.

Value

A list which is an object of the class `geodata`.

See Also

- `subset` for the generic function and methods and `as.geodata` for more information on `geodata` objects.

Examples

```r
subset(ca20, data > 70)
subset(ca20, area == 1)
```

---

**summary.geodata**

**Summaries for geodata object**

Description

Summarises each of the main elements of an object of the class `geodata`.

Usage

```r
## S3 method for class 'geodata'
summary(object, lambda = 1, add.to.data = 0,
         by.realisations=TRUE, ...)
```

Arguments

- `object`: an object of the class `geodata`.
- `lambda`: value of the Box-Cox transformation parameter. Two particular cases are \( \lambda = 1 \) which corresponds to no transformation and \( \lambda = 0 \) corresponding to the log-transformation.
- `add.to.data`: scalar, Constant value to be added to the data values. Only used if a value different from 1 is passed to the argument `lambda`.
by.realisations

logical. Indicates whether the summary must be performed separately for each
realisation, if the geodata object contains the element realisations. Defaults
to TRUE.

... further arguments to be passed to the function summary.default.

Value

A list with components

- coords.summary
  a matrix with minimum and maximum values for the coordinates.
- distances.summary
  minimum and maximum distances between pairs of points.
- borders.summary
  a matrix with minimum and maximum values for the coordinates. Only returned
  if there is an element borders in the geodata object.
- data.summary
  summary statistics (min, max, quartiles and mean) for the data.
- units.m.summary
  summary statistics (min, max, quartiles and mean) for the offset variable. Only
  returned if there is an element units.m in the geodata object.
- covariate.summary
  summary statistics (min, max, quartiles and mean) for the covariate(s). Only
  returned if there is an element covariate in the geodata object.
- others
  names of other elements if present in the geodata object.

Examples

summary(s100)
summary(ca20)
summary.likGRF

**Summarizes Parameter Estimation Results for Gaussian Random Fields**

**Description**

Summarizes results returned by the function `likfit`. Functions are *methods* for `summary` and `print` for the classes `likGRF` and `summary.likGRF`.

**Usage**

```r
## S3 method for class 'likGRF'
summary(object, ...)  
## S3 method for class 'likGRF'
print(x, digits = max(3, getOption("digits") - 3), ...)  
## S3 method for class 'summary.likGRF'
print(x, digits = max(3, getOption("digits") - 3), ...)  
```

**Arguments**

- `object` an object of class `likGRF`, typically a result of a call to `likfit`.
- `x` an object of class `likGRF` or class `summary.likGRF`, typically resulting from a call to `likfit`.
- `digits` the number of significant digits to use when printing.
- `...` extra arguments for `print`.

**Details**

A detailed summary of an object of the class `likGRF` is produced by `summary.likGRF` and printed by `print.summary.likGRF`. This includes model specification with values of fixed and estimated parameters. A simplified summary of the parameter estimation is printed by `print.likGRF`.

**Value**

- `print.likGRF` prints the parameter estimates and the value of the maximized likelihood.
- `summary.likGRF` returns a list with main results of a call to `likfit`.
- `print.summary.likGRF` prints these results on the screen (or other output device) in a "nice" format.

summary.variofit

Description

This function prints a summary of the parameter estimation results given by variofit.

Usage

## S3 method for class 'variofit'
summary(object, ...)

Arguments

object an object of the class "variomodel" typically an output of variofit.
...
other arguments to be passed to the function print or summary.

Value

Prints a summary of the estimation results on the screen or other output device.

wls <- variofit(s100.vario, ini=c(.5, .5), fix.nugget = TRUE)
wls
summary(wls)
tce

*TCE concentrations in groundwater in a vertical cross section*

**Description**

Measurements at 56 locations of concentration of trichloroethylene (TCE) in groundwater on a transect in a fine-sand superficial aquifer. Extract from Kitanidis’ book.

**Usage**

```r
data(tce)
```

**Format**

An object of the class `geodata` which is a list with the elements:

- `coords` coordinates of the data location (feet).
- `data` the data vector with measurements of the TCE concentration (ppb).

**Source**

**Examples**

```r
summary(tce)
summary(tce, lambda=0)
plot(tce)
points(tce)
points(tce, lambda=0)
```

trend.spatial

*Builds the Trend Matrix*

**Description**

Builds the `trend` matrix in accordance to a specification of the mean provided by the user.

**Usage**

```r
trend.spatial(trend, geodata, add.to.trend)
```
Arguments

trend specifies the mean part of the model. See DETAILS below.

trend

gedata optional. An object of the class geodata as described in as.geodata.
geodata

add.to.trend optional. Specifies additional terms to the mean part of the model. See details below.
add.to.trend

Details

The implicit model assumes that there is an underlying process with mean \( \mu(x) \), where \( x = (x_1, x_2) \) denotes the coordinates of a spatial location. The argument trend defines the form of the mean and the following options are allowed:

- "cte" the mean is assumed to be constant over the region, in which case \( \mu(x) = \mu \). This is the default option.
- "1st" the mean is assumed to be a first order polynomial on the coordinates:
\[
\mu(x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2
\]
- "2nd" the mean is assumed to be a second order polynomial on the coordinates:
\[
\mu(x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 (x_1)^2 + \beta_4 (x_2)^2 + \beta_5 x_1 \times x_2
\]
- ~ model a model specification. See formula for further details on how to specify a model in R using formulas. Notice that the model term before the ~ is not necessary. Typically used to include covariates (external trend) in the model.

Denote by \( x_1 \) and \( x_2 \) the spatial coordinates. The following specifications are equivalent:

- trend = "1st" and trend = ~ x1 + x2
- trend = "2nd" and trend = ~ x1 + x2 + I(x1^2) + I(x2^2) + I(x1*x2)

Search path for covariates

Typically, functions in the package geor which calls trend.spatial will have the arguments geodata, coords and data.

When the trend is specified as trend = ~ model the terms included in the model will be searched for in the following path sequence (in this order):

1. in the users/session Global environment
2. in the session search path
3. as elements of the list geodata
4. as columns in a data-frame geodata$covariates
5. as columns in a data-frame geodata$data
6. in remainder of the session search path

The argument add.to.trend adds terms to what is specified in the argument trend. This seems redundant but allow specifications of the type: trend="2nd", add.trend=~other.covariates.
Value

An object of the class trend.spatial which is an $n \times p$ trend matrix, where $n$ is the number of spatial locations and $p$ is the number of mean parameters in the model.

Note

This is an auxiliary function typically called by other geoR functions.

trend.spatial("2nd", sic.100, add="altitude"[1:5,

---

varcov.spatial

Computes Covariance Matrix and Related Results

Description

This function builds the covariance matrix for a set of spatial locations, given the covariance parameters. According to the input options other results related to the covariance matrix (such as decompositions, determinants, inverse, etc) can also be returned.
Usage

varcov.spatial(coords = NULL, dists.lowertri = NULL, 
cov.model = "matern", kappa = 0.5, nugget = 0, 
cov.pars = stop("no cov.pars argument"), 
inv = FALSE, det = FALSE, 
func.inv = c("cholesky", "eigen", "svd", "solve"), 
scaled = FALSE, only.decomposition = FALSE, 
sqrt.inv = FALSE, try.another.decomposition = TRUE, 
only.inv.lower.diag = FALSE, ...)

Arguments

cords an \( n \times 2 \) matrix with the coordinates of the data locations. If not provided the argument dists.lowertri should be provided instead.
dists.lowertri a vector with the lower triangle of the matrix of distances between pairs of data points. If not provided the argument coords should be provided instead.
cov.model a string indicating the type of the correlation function. More details in the documentation for cov.spatial. Defaults are equivalent to the exponential model.
kappa values of the additional smoothness parameter, only required by the following correlation functions: "matern", "powered.exponential", "cauchy" and "gneiting.matern".
nugget the value of the nugget parameter \( \tau^2 \).
cov.pars a vector with 2 elements or an \( ns \times 2 \) matrix with the covariance parameters. The first element (if a vector) or first column (if a matrix) corresponds to the variance parameter \( \sigma^2 \). second element or column corresponds to the correlation function parameter \( \phi \). If a matrix is provided each row corresponds to the parameters of one spatial structure. Models with several structures are also called nested models in the geostatistical literature.
inv if TRUE the inverse of covariance matrix is returned. Defaults to FALSE.
det if TRUE the logarithmic of the square root of the determinant of the covariance matrix is returned. Defaults to FALSE.
func.inv algorithm used for the decomposition and inversion of the covariance matrix. Options are "cholesky" for Cholesky decomposition, "svd" for singular value decomposition and "eigen" for eigenvalues/eigenvectors decomposition. Defaults to "cholesky".
scaled logical indicating whether the covariance matrix should be scaled. If TRUE the partial sill parameter \( \sigma^2 \) is set to 1. Defaults to FALSE.
only.decomposition logical. If TRUE only the square root of the covariance matrix is returned. Defaults to FALSE.
sqrt.inv if TRUE the square root of the inverse of covariance matrix is returned. Defaults to FALSE.
try.another.decomposition

logical. If TRUE and the argument func.inv is one of "cholesky", "svd" or "solve", the matrix decomposition or inversion is tested and, if it fails, the argument func.inv is re-set to "eigen".

only.inv.lower.diag

logical. If TRUE only the lower triangle and the diagonal of the inverse of the covariance matrix are returned. Defaults to FALSE.

... for now, only for internal usage.

Details

The elements of the covariance matrix are computed by the function \texttt{cov.spatial}. Typically this is an auxiliary function called by other functions in the \texttt{geoR} package.

Value

The result is always list. The components will vary according to the input options. The possible components are:

\begin{verbatim}
varcov            the covariance matrix.
sqrt.varcov       a square root of the covariance matrix.
lower.inverse     the lower triangle of the inverse of covariance matrix.
diag.inverse      the diagonal of the inverse of covariance matrix.
inverse           the inverse of covariance matrix.
sqrt.inverse      a square root of the inverse of covariance matrix.
log.det.to.half   the logarithmic of the square root of the determinant of the covariance matrix.
\end{verbatim}

\url{http://www.leg.ufpr.br/geoR}.

See Also

cov.spatial for more information on the correlation functions; chol, solve, svd and eigen for matrix inversion and/or decomposition.
Description

Covariance matrix for the bivariate Gaussian common component geostatistical model or its inverse, and optionally the determinant of the matrix.

Usage

```r
varcovBGCCM(dists.obj, cov0.pars, cov1.pars, cov2.pars,
  cov0.model = "matern", cov1.model = "matern",
  cov2.model = "matern", kappa0 = 0.5, kappa1 = 0.5,
  kappa2 = 0.5, scaled = TRUE, inv = FALSE, det = FALSE)
```

Arguments

dists.obj: a vector with distance values
cov0.pars: covariance parameter values for the common component
cov1.pars: covariance parameter for the individual structure of the first variable
cov2.pars: covariance parameter for the individual structure of the second variable
cov0.model: character indicating a valid correlation model
cov1.model: character indicating a valid correlation model
cov2.model: character indicating a valid correlation model
kappa0: scalar
kappa1: scalar
kappa2: scalar
scaled: logical
inv: logical. If TRUE the inverse of the covariance matrix is returned instead.
det: logical. Optional, if TRUE the logarithm of the determinant of the covariance matrix is returned as an attribute.

Value

A matrix which is the covariance matrix for the bivariate Gaussian common component geostatistical model or its inverse if inv=TRUE. If det=T the logarithm of the determinant of the matrix is also returned as an attribute named logdetS.

Warning

This is a new function and still in draft format and pretty much untested.

Examples

# see http://www.leg.ufpr.br/geoR/tutorials/CCM.R

---

**Description**

Estimate covariance parameters by fitting a parametric model to an empirical variogram. Variograms models can be fitted by using weighted or ordinary least squares.

**Usage**

```r
variofit(vario, ini.cov.pars, cov.model,
    fix.nugget = FALSE, nugget = 0,
    fix.kappa = TRUE, kappa = 0.5,
    simul.number = NULL, max.dist = vario$max.dist,
    weights, minimisation.function,
    limits = pars.limits(), messages, ...)
```

**Arguments**

- `vario`: an object of the class "variogram", typically an output of the function `variog`. The object is a list with information about the empirical variogram.
- `ini.cov.pars`: initial values for the covariance parameters: $\sigma^2$ (partial sill) and $\phi$ (range parameter). See DETAILS below.
- `cov.model`: a string with the name of the correlation function. For further details see documentation for `cov.spatial`. For the linear model use `cov.model = "linear"`. Read values from variomodel object passed `ini.cov.pars`, otherwise default is the `exponential` model.
- `fix.nugget`: logical, indicating whether the parameter $\tau^2$ (nugget variance) should be regarded as fixed (`fix.nugget = TRUE`) or should be estimated (`fix.nugget = FALSE`). Defaults to `FALSE`.
- `nugget`: value for the nugget parameter. Regarded as a fixed values if `fix.nugget = TRUE` or as a initial value for the minimization algorithm if `fix.nugget = FALSE`. Defaults to zero.
fix.kappa  logical, indicating whether the parameter $\kappa$ should be regarded as fixed or be estimated. Defaults to TRUE.
kappa  value of the smoothness parameter. Regarded as a fixed values if fix.kappa = TRUE or as a initial value for the minimization algorithm if fix.kappa = FALSE. Only required if one of the following correlation functions is used: "matern", "powered.exponential", "cauchy" and "gneiting.matern". Defaults to 0.5.
simul.number  number of simulation. To be used when the object passed to the argument vario has empirical variograms for more than one data-set (or simulation). Indicates to which one the model will be fitted.
max.dist  maximum distance considered when fitting the variogram. Defaults to vario$max.dist.
weights  type weights used in the loss function. See DETAILS below.
limits  values defining lower and upper limits for the model parameters used in the numerical minimisation. Only valid if minimisation.function = "optim". The auxiliary function pars.limits is called to set the limits.
minimisation.function  minimization function used to estimate the parameters. Options are "optim", "nlm". If weights = "equal" the option "nls" is also valid and det as default. Otherwise defaults to "optim".
messages  logical. Indicates whether or not status messages are printed on the screen (or other output device) while the function is running.
...  further parameters to be passed to the minimization function. Typically arguments of the type control() which controls the behavior of the minimization algorithm. See documentation for the selected minimization function for further details.

Details

Numerical minimization

The parameter values are found by numerical optimization using one of the functions: optim, nlm and nls. In given circumstances the algorithm may not converge to correct parameter values when called with default options and the user may need to pass extra options for the optimizers. For instance the function optim takes a control argument. The user should try different initial values and if the parameters have different orders of magnitude may need to use options to scale the parameters. Some possible workarounds in case of problems include:

- rescale you data values (dividing by a constant, say)
- rescale your coordinates (subtracting values and/or dividing by constants)
- Use the mechanism to pass control() options for the optimiser internally

Initial values

The algorithms for minimization functions require initial values of the parameters.

A unique initial value is used if a vector is provided in the argument ini.cov.pars. The elements are initial values for $\sigma^2$ and $\phi$, respectively. This vector is concatenated with the value of the argument nugget if fix.nugget = FALSE and kappa if fix.kappa = TRUE.

Specification of multiple initial values is also possible. If this is the case, the function searches for the one which minimizes the loss function and uses this as the initial value for the minimization
Algorithm. Multiple initial values are specified by providing a matrix in the argument ini.cov.pars and/or, vectors in the arguments nugget and kappa (if included in the estimation). If ini.cov.pars is a matrix, the first column has values of $\sigma^2$ and the second has values of $\phi$.

Alternatively the argument ini.cov.pars can take an object of the class eyefit or variomodel. This allows the usage of an output of the functions eyefit, variofit or likfit be used as initial value.

If minimisation.function = "nls" only the values of $\phi$ and $\kappa$ (if this is included in the estimation) are used. Values for the remaining are not need by the algorithm.

If cov.model = "linear" only the value of $\sigma^2$ is used. Values for the remaning are not need by this algorithm.

If cov.model = "pure.nugget" no initial values are needed since no minimisation function is used.

Weights

The different options for the argument weights are used to define the loss function to be minimised. The available options are as follows.

"npairs" indicates that the weights are given by the number of pairs in each bin. This is the default option unless variog$output.type = "cloud". The loss function is:

$$LOSS(\theta) = \sum_k n_k [(\hat{\gamma}_k) - \gamma_k(\theta)]^2$$

"cressie" weights as suggested by Cressie (1985).

$$LOSS(\theta) = \sum_k n_k [\frac{(\hat{\gamma}_k) - \gamma_k(\theta)}{\gamma_k(\theta)}]^2$$

"equal" equal values for the weights. For this case the estimation corresponds to the ordinary least squares variogram fitting. This is the default option if variog$output.type = "cloud". The loss function is:

$$LOSS(\theta) = \sum_k [(\hat{\gamma}_k) - \gamma_k(\theta)]^2$$

Where $\theta$ is the vector with the variogram parameters and for each $k^{th}$ bin $n_k$ is the number of pairs, $(\hat{\gamma}_k)$ is the value of the empirical variogram and $\gamma_k(\theta)$ is the value of the theoretical variogram.

See also Cressie (1993) and Barry, Crowder and Diggle (1997) for further discussions on methods to estimate the variogram parameters.

Value

An object of the class "variomodel" and "variofit" which is list with the following components:

- nugget: value of the nugget parameter. An estimated value if fix.nugget = FALSE or a fixed value if fix.nugget = TRUE.
- cov.pars: a two elements vector with estimated values of the covariance parameters $\sigma^2$ and $\phi$, respectively.
variofit

cov.model  a string with the name of the correlation function.
kappa      fixed value of the smoothness parameter.
value      minimized value of the loss function.
max.dist   maximum distance considered in the variogram fitting.
minimisation.function
weights    minimization function used.
method     a string indicating the type of weights used for the variogram fitting.
fix.kappa  a string indicating the type of variogram fitting method (OLS or WLS).
fix.nugget logical indicating whether the parameter $\kappa$ was fixed.
lambda     logical indicating whether the nugget parameter was fixed.
message    transformation parameters inherit from the object provided in the argument vario.
call       status messages returned by the function.

Peter J. Diggle <p.diggle@lancaster.ac.uk>.

References

Further information on the package geoR can be found at: http://www.leg.ufpr.br/geoR.

See Also

cov.spatial for a detailed description of the available correlation (variogram) functions, likfit for maximum and restricted maximum likelihood estimation, lines.variogram for graphical output of the fitted model. For details on the minimization functions see optim, nlm and nls.

Examples

```r
vario100 <- variog(s100, max.dist=1)
ini.vals <- expand.grid(seq(0,1,1=5), seq(0,1,1=5))
ols <- variofit(vario100, ini=ini.vals, fix.nug=TRUE, wei="equal")
summary(ols)
wls <- variofit(vario100, ini=ini.vals, fix.nug=TRUE)
summary(wls)
plot(vario100)
lines(wls)
lines(ols, lty=2)
```
Computes sample (empirical) variograms with options for the classical or robust estimators. Output can be returned as a binned variogram, a variogram cloud or a smoothed variogram. Data transformation (Box-Cox) is allowed. “Trends” can be specified and are fitted by ordinary least squares in which case the variograms are computed using the residuals.

Usage

```r
variog(geodata, coords = geodata$coords, data = geodata$data,
       uvec = "default", breaks = "default",
       trend = "cte", lambda = 1,
       option = c("bin", "cloud", "smooth"),
       estimator.type = c("classical", "modulus"),
       nugget.tolerance, max.dist, pairs.min = 2,
       bin.cloud = FALSE, direction = "omnidirectional", tolerance = pi/8,
       unit.angle = c("radians","degrees"), angles = FALSE, messages, ...)
```

Arguments

- `geodata` a list containing element `coords` as described next. Typically an object of the class "geodata" - a `geoR` data-set. If not provided the arguments `coords` must be provided instead.
- `coords` an n × 2 matrix containing coordinates of the n data locations in each row. Defaults to `geodata$coords`, if provided.
- `data` a vector or matrix with data values. If a matrix is provided, each column is regarded as one variable or realization. Defaults to `geodata$data`, if provided.
- `uvec` a vector with values used to define the variogram binning. Only used when `option = "bin"`. See DETAILS below for more details on how to specify the bins.
- `breaks` a vector with values to define the variogram binning. Only used when `option = "bin"`. See DETAILS below for more details on how to specify the bins.
- `trend` specifies the mean part of the model. See documentation of `trend.spatial` for further details. Defaults to "cte".
- `lambda` values of the Box-Cox transformation parameter. Defaults to 1 (no transformation). If another value is provided the variogram is computed after transforming the data. A case of particular interest is λ = 0 which corresponds to log-transformation.
option defines the output type: the options "bin" returns values of binned variogram, "cloud" returns the variogram cloud and "smooth" returns the kernel smoothed variogram. Defaults to "bin".

estimator.type "classical" computes the classical method of moments estimator. "modulus" returns the variogram estimator suggested by Hawkins and Cressie (see Cressie, 1993, pg 75). Defaults to "classical".

nugget.tolerance a numeric value. Points which are separated by a distance less than this value are considered co-located. Defaults to zero.

max.dist a numerical value defining the maximum distance for the variogram. Pairs of locations separated for distance larger than this value are ignored for the variogram calculation. If not provided defaults takes the maximum distance among all pairs of data locations.

pairs.min a integer number defining the minimum numbers of pairs for the bins. For option = "bin", bins with number of pairs smaller than this value are ignored. Defaults to NULL.

bin.cloud logical. If TRUE and option = "bin" the cloud values for each class are included in the output. Defaults to FALSE.

direction a numerical value for the directional (azimuth) angle. This used to specify directional variograms. Default defines the omnidirectional variogram. The value must be in the interval \([0, \pi]\) radians \((0, 180)\) degrees).

tolerance numerical value for the tolerance angle, when computing directional variograms. The value must be in the interval \([0, \pi/2]\) radians \((0, 90)\) degrees). Defaults to \(\pi/8\).

unit.angle defines the unit for the specification of angles in the two previous arguments. Options are "radians" and "degrees", with default to "radians".

angles Logical with default to FALSE. If TRUE the function also returns the angles between the pairs of points (unimplemented).

messages logical. Indicates whether status messages should be printed on the screen (or output device) while the function is running.

... arguments to be passed to the function ksmooth, if option = "smooth".

Details

Variograms are widely used in geostatistical analysis for exploratory purposes, to estimate covariance parameters and/or to compare theoretical and fitted models against sample variograms.

Estimators

The two estimators currently implemented are:

- **classical** (method of moments) estimator:

  \[
  \gamma(h) = \frac{1}{2Nh} \sum_{i=1}^{N_i} [Y(x_{i+h}) - Y(x_i)]^2
  \]
Hawkins and Cressie’s modulus estimator  
\[
\gamma(h) = \left[ \frac{1}{N_h} \sum_{i=1}^{N_h} |Y(x_i+h) - Y(x_i)|^2 \right]^{1/4} 
0.914 + 0.988 \frac{1}{N_h}
\]

**Defining the bins**

The defaults  
If arguments `breaks` and `uvec` are not provided, the binning is defined as follows:

1. read the argument `max.dist`. If not provided it is set to the maximum distance between the pairs of points.
2. the center of the bins are initially defined by the sequence \( u = \text{seq}(0, \max.dist, 1 = 13) \).
3. the interval spanned by each bin is given by the mid-points between the centers of the bins.

If a vector is passed to the argument `breaks` its elements are taken as the limits of the bins (classes of distance) and the argument `uvec` is ignored.

Variations on the default  
The default definition of the bins is different for some particular cases.

1. if there are coincident data locations the bins follows the default above but one more bin is added at the origin (distance zero) for the collocated points.
2. if the argument `nugget.tolerance` is provided the separation distance between all pairs in the interval \([0, \text{nugget.tolerance}]\) are set to zero. The first bin distance is set to zero \((u[1] = \emptyset)\). The remaining bins follows the default.
3. if a scalar is provided to the argument `uvec` the default number of bins is defined by this number.
4. if a vector is provided to the argument `uvec`, its elements are taken as central points of the bins.

**Value**

An object of the `class` `variogram` which is a list with the following components:

- `u` a vector with distances.
- `v` a vector with estimated variogram values at distances given in `u`.
- `n` number of pairs in each bin, if `option = "bin"`.
- `sd` standard deviation of the values in each bin.
- `bins.lim` limits defining the interval spanned by each bin.
- `ind.bin` a logical vector indicating whether the number of pairs in each bin is greater or equal to the value in the argument `pairs.min`.
- `var.mark` variance of the data.
- `beta.ols` parameters of the mean part of the model fitted by ordinary least squares.
- `output.type` echoes the option argument.
- `max.dist` maximum distance between pairs allowed in the variogram calculations.
estimator.type  
  echoes the type of estimator used.

n.data  
  number of data.

lambda  
  value of the transformation parameter.

trend  
  trend specification.

nugget.tolerance  
  value of the nugget tolerance argument.

direction  
  direction for which the variogram was computed.

tolerance  
  tolerance angle for directional variogram.

uvec  
  lags provided in the function call.

call  
  the function call.

legend("topleft", legend=c("omnidirectional", expression(0 * degree)), lty=c(2,1))

---

### variog.mc.env

![Envelops for Empirical Variograms Based on Permutation](image)

#### Description

Computes envelopes for empirical variograms by permutation of the data values on the spatial locations.

#### Usage

```r
c0.0 <- variog(s=100, max.dist=1, dir=0, tol=pi/8)
plot(vario.b, type="l", lty=2)
lines(vario.0)
legend("topleft", legend=c("omnidirectional", expression(0 * degree)), lty=c(2,1))
```

#### Arguments

- `geodata`: a list containing elements `coords` and `data` as described next. Typically an object of the class "geodata" - a `geoR` data-set. If not provided the arguments `coords` and `data` must be provided instead.
- `coords`: an \( n \times 2 \) matrix, each row containing Euclidean coordinates of the \( n \) data locations. By default it takes the element `coords` of the argument `geodata`.
- `data`: a vector with the data values. By default it takes the element `data` of the argument `geodata`.
- `obj.vario`: an object of the class "variogram", typically an output of the function `variog`.
- `nsim`: number of simulations used to compute the envelope. Defaults to 99.
- `save.sim`: logical. Indicates whether or not the simulated data are included in the output. Defaults to FALSE.
- `messages`: logical. If TRUE, the default, status messages are printed while the function is running.

#### Details

The envelopes are obtained by permutation. For each simulations data values are randomly allocated to the spatial locations. The empirical variogram is computed for each simulation using the same lags as for the variogram originally computed for the data. The envelopes are computed by taking, at each lag, the maximum and minimum values of the variograms for the simulated data.
**Value**

An object of the `class"variogram.envelope"` which is a list with the following components:

- `u` a vector with distances.
- `v.lower` a vector with the minimum variogram values at each distance in `u`.
- `v.upper` a vector with the maximum variogram values at each distance in `u`.
- `simulations` a matrix with simulated data. Only returned if `save.sim = TRUE`.

**Author(s)**

Paulo Justiniano Ribeiro Jr. <paulojus@leg.ufpr.br>,
Peter J. Diggle <p.diggle@lancaster.ac.uk>.

**References**

Further information on the package `geoR` can be found at:
[http://www.leg.ufpr.br/geoR](http://www.leg.ufpr.br/geoR).

**See Also**

- `variog.model.env` for envelopes computed by from a model specification, `variog` for variogram calculations, `plot.variogram` and `variog.mc.env` for graphical output.

**Examples**

```r
s100.vario <- variog(s100, max.dist=1)
s100.env <- variog.mc.env(s100, obj.var = s100.vario)
plot(s100.vario, envelope = s100.env)
```

**Description**

Computes envelopes for a empirical variogram by simulating data for given model parameters.
Computes bootstrap paremeter estimates

**Usage**

```r
variog.model.env(geodata, coords = geodata$coords, obj.variog, 
model.pars, nsim = 99, save.sim = FALSE, messages)

boot.variofit(geodata, coords = geodata$coords, obj.variog, 
model.pars, nsim = 99, trace = FALSE, messages)
```
Arguments

geodata a list containing element coords as described next. Typically an object of the class "geodata" - a geOR data-set. If not provided the argument coords must be provided instead.

coords an $n \times 2$ matrix, each row containing Euclidean coordinates of the $n$ data locations. By default it takes the element coords of the argument geodata.

obj.variog an object of the class "variogram", typically an output of the function variog.

model.pars a list with model specification and parameter values. The input is typically an object of the class variomodel which is an output of likfit, variofit. The required components of the list are:

- beta, the mean parameter. Defaults to zero.
- cov.model, the covariance model. Defaults to "exponential".
- cov.pars, the covariance parameters $\sigma^2$ and $\phi$.
- kappa, the extra covariance parameters for some of the covariance models. Defaults to 0.5.
- nugget, the error component variance. Defaults to zero.
- estimator.type, the type of variogram estimator. Options for "classical" and "robust". Defaults to obj.variog$estimator.

nsim number of simulations used to compute the envelopes. Defaults to 99.

save.sim logical. Indicates whether or not the simulated data are included in the output. Defaults to FALSE.

trace logical. If TRUE the fitted values for the bootstrap parameter estimation are printed while the function is running.

messages logical. If TRUE, the default, status messages are printed while the function is running.

Details

The envelopes are computed assuming a (transformed) Gaussian random field model. Simulated values are generated at the data locations, given the model parameters. The empirical variogram is computed for each simulation using the same lags as for the original variogram of the data. The envelopes are computed by taking, at each lag, the maximum and minimum values of the variograms for the simulated data.

Value

An object of the class "variogram.envelope" which is a list with the components:

- u a vector with distances.
- v.lower a vector with the minimum variogram values at each distance in u.
- v.upper a vector with the maximum variogram values at each distance in u.
- simulations a matrix with the simulated data. Only returned if save.sim = TRUE.
variog4

plot(s100.vario, env = s100.env)

---

variog4 Computes Directional Variograms

Description

Computes directional variograms for 4 directions provided by the user.

Usage

variog4(geodata, coords = geodata$coords, data = geodata$data,
         uvec = "default", breaks = "default", trend = "cte", lambda = 1,
         option = c("bin", "cloud", "smooth"),
         estimator.type = c("classical", "modulus"),
         nugget.tolerance, max.dist, pairs.min = 2,
         bin.cloud = FALSE, direction = c(0, pi/4, pi/2, 3*pi/4), tolerance = pi/8,
         unit.angle = c("radians", "degrees"), messages, ...)

Arguments

geodata a list containing element coords as described next. Typically an object of the class "geodata" - a geoR data-set. If not provided the arguments coords must be provided instead.

coords an $n \times 2$ matrix containing coordinates of the $n$ data locations in each row. Defaults to geodata$coords, if provided.
data a vector or matrix with data values. If a matrix is provided, each column is regarded as one variable or realization. Defaults to geodata$data, if provided.

uvec a vector with values to define the variogram binning. For further details see documentation for variog.

breaks a vector with values to define the variogram binning. For further details see documentation for variog.

trend specifies the mean part of the model. The options are: "cte" (constant mean), "1st" (a first order polynomial on the coordinates), "2nd" (a second order polynomial on the coordinates), or a formula of the type ~X where X is a matrix with the covariates (external trend). Defaults to "cte".

lambda values of the Box-Cox transformation parameter. Defaults to 1 (no transformation). If another value is provided the variogram is computed after transforming the data. A case of particular interest is \( \lambda = 0 \) which corresponds to log-transformation.

option defines the output type: the options "bin" returns values of binned variogram, "cloud" returns the variogram cloud and "smooth" returns the kernel smoothed variogram. Defaults to "bin".

estimator.type "classical" computes the classical method of moments estimator. "modulus" returns the variogram estimator suggested by Hawkins and Cressie (see Cressie, 1993, pg 75). Defaults to "classical".

nugget.tolerance a numeric value. Points which are separated by a distance less than this value are considered co-located. Defaults to zero.

max.dist a numerical value defining the maximum distance for the variogram. Pairs of locations separated for distance larger than this value are ignored for the variogram calculation. Defaults to the maximum distance among the pairs of data locations.

pairs.min a integer number defining the minimum numbers of pairs for the bins. For option = "bin", bins with number of pairs smaller than this value are ignored. Defaults to NULL.

bin.cloud logical. If TRUE and option = "bin" the cloud values for each class are included in the output. Defaults to FALSE.

direction a vector with values of 4 angles, indicating the directions for which the variograms will be computed. Default corresponds to \( c(0, 45, 90, 135) \) (degrees).

tolerance numerical value for the tolerance angle, when computing directional variograms. The value must be in the interval \([0, 90]\) degrees. Defaults to \( \pi/8 \).

unit.angle defines the unit for the specification of angles in the two previous arguments. Options are "degrees" and "radians".

messages logical. Indicates whether status messages should be printed on the screen (or output device) while the function is running.

... arguments to be passed to the function ksmooth, if option = "smooth".
Value

The output is an object of the class `variog4`, a list with five components. The first four elements are estimated variograms for the directions provided and the last is the omnidirectional variogram. Each individual component is an object of the class `variogram`, an output of the function `variog`.

See Also

`variog` for variogram calculations and `plot.variog4` for plotting results.

Examples

```r
var4 <- variog4(s100, max.dist=1)
plot(var4)
```

Description

Data used in Chapter 8, page 156 of Webster and Oliver (2001) to illustrate properties of the kriging predictor.

Usage

data(wo)

Format

An object of the class `geodata` which is a list with the elements:

- `coords` coordinates of the data location.
- `data` the data vector.
- `x1` coordinate of the centrally located prediction point.
- `x2` coordinate of the off-centre prediction point.

Source

## Examples

```r
attach(wo)
par(mfrow=c(1,2))
plot(c(-10,130), c(-10,130), ty="n", asp=1)
points(rbind(coords, x1))
text(coords[,1], 5+coords[,2], format(data))
text(x1[1]+5, x1[2]+5, "?", col=2)
plot(c(-10,130), c(-10,130), ty="n", asp=1)
points(rbind(coords, x2))
text(coords[,1], 5+coords[,2], format(data))
text(x2[1]+5, x2[2]+5, "?", col=2)
```

## Wolfcamp Aquifer Data

### Description

Piezometric head measurements taken at the Wolfcamp Aquifer, Texas, USA. See Cressie (1993, p.212–214) for description of the scientific problem and the data. Original data were converted to SI units: coordinates are given in kilometers and pressure heads to meters.

### Usage

```r
data(wolfcamp)
```

### Format

An object of the class "geodata", which is list with two components:

- `coords` the coordinates of the data locations. The distance are given in kilometers.
- `data` values of the piezometric head. The unit is heads to meters.

### Source

### References

```r
summary(wolfcamp)
plot(wolfcamp)
```
Wrappers for the C functions used in geoR

Description

These functions are wrappers for some (but not all) the C functions included in the geoR package. Typically the C code is directly called from the geoR functions but these functions allows independent calls.

Usage

diffpairs(coords, data)
loccoords(coords, locations)
.diagquadraticformXAX(X, lowerA, diagA)
.bilinearformXAY(X, lowerA, diagA, Y)
.corr.diaglowertri(coords, cov.model, phi, kappa)
.Ccor.spatial(x, phi, kappa, cov.model)

Arguments

coops an $n \times 2$ matrix with the data coordinates.
data an vector with the data values.
locations an $N \times 2$ matrix with the coordinates of the prediction locations.
lowerA a vector with the diagonal terms of the symmetric matrix A.
diagA a vector with the diagonal terms of the symmetric matrix A.
X a matrix with conforming dimensions.
Y a matrix with conforming dimensions.
cov.model covariance model, see cov.spatial for options and more details.
phi numerical value of the correlation function parameter phi.
kappa numerical value of the correlation function parameter kappa.
x a vector of distances.

Value

The outputs for the different functions are:
diffpairs returns a list with elements dist - the distance between pairs of points, and diff - the difference between the values of the attributes.
loccoords returns a $n \times N$ matrix with distances between data points and prediction locations.
diagquadraticformXAX returns a vector with the diagonal term of the quadratic form $X'AX$. 
bilinearformXAY
returns a vector or a matrix with the terms of the quadratic form $X'AY$.
corr.diaglowertri
returns the lower triangle of the correlation matrix, including the diagonal.
Ccor.spatial returns a vector of values of spatial correlations.

**wrc**

**Points of a water retention curve data set**

**Description**

Soil density and measures of the water retention curve obtained at different pressures on a regular grid with 10x25 points spaced by 5 meters.

**Usage**

data(wrc)

**Format**

A data frame with 250 observations on the following 11 variables.

- **CoordX**: a numeric vector with the X coordinates of the samples.
- **CoordY**: a numeric vector with the Y coordinate of the samples.
- **Densidade**: a numeric vector, soil density $(g/cm^3)$
- **Pr5**: a numeric vector, water content at a pressure of 5 mca – $5 \times 10^2$ Pa (atm)
- **Pr10**: a numeric vector, water content at a pressure of 10 mca – $1 \times 10^3$ Pa (atm)
- **Pr60**: a numeric vector, water content at a pressure of 60 mca – $6 \times 10^3$ Pa (atm)
- **Pr100**: a numeric vector, water content at a pressure of 100 mca – $1 \times 10^4$ Pa (atm)
- **Pr306**: a numeric vector, water content at a pressure of 306 mca – $3 \times 10^4$ Pa (atm)
- **Pr816**: a numeric vector, water content at a pressure of 816 mca – $8 \times 10^4$ Pa (atm)
- **Pr3060**: a numeric vector, water content at a pressure of 3060 mca – $3 \times 10^5$ Pa (atm)
- **Pr15300**: a numeric vector, water content at a pressure of 15300 mca – $1.5 \times 10^6$ Pa (atm)
Details

Uniformity trial with 250 undisturbed soil samples collected at 25cm soil depth of spacing of 5 meters, resulting on a regular grid of $25 \times 10$ sampling points.

For each sampling point there are measurements of the soil density and water content obtained at eight pressures: 5, 10, 60, 100, 306, 816, 3060 and 15300 meters of column of water (mca), corresponding to $5 \times 10^2$, $1 \times 10^3$, $6 \times 10^3$, $1 \times 10^4$, $3 \times 10^4$, $8 \times 10^4$, $3 \times 10^5$, $1.5 \times 10^6$ Pa.

The experiment aimed to use the water contents of the samples to estimate the water retention curve at the 250 data points.

See also the data-set soil1250 with soil chemistry properties measured at the same points.

summary(pr100)
plot(pr100)
```

---

**xvalid** 

*Cross-validation by kriging*

**Description**

A function to perform model validation by comparing observed and values predicted by kriging. Options include: (i) *leaving-one-out* cross-validation where each data location is removed from the data set and the variable at this location is predicted using the remaining locations, for a given model. This can be computed for all or a subset of the data locations; (ii) *external validation* can be performed by using validation locations other than data locations.
Usage

xvalid(geodata, coords = geodata$coords, data = geodata$data,
model, reestimate = FALSE, variog.obj = NULL,
output.reestimate = FALSE, locations.xvalid = "all",
data.xvalid = NULL, messages, ...)

Arguments

geodata a list containing element coords as described next. Typically an object of the class "geodata" - a geoR data-set. If not provided the arguments coords must be provided instead.

coords an $n \times 2$ matrix containing coordinates of the $n$ data locations in each row. Defaults to geodata$coords, if provided.

data a vector or matrix with data values. If a matrix is provided, each column is regarded as one variable or realization. Defaults to geodata$data, if provided.

model an object containing information on a fitted model. Typically an output of likfit, variofit. If an object of the class eyefit is passed it takes the first model specified in the object.

reestimate logical. Indicates whether or not the model parameters should be re-estimated for each point removed from the data-set.

variog.obj on object with the empirical variogram, typically an output of the function variog. Only used if reestimate = TRUE and the object passed to the argument model is the result of a variogram based estimation, i.e. if the model was fitted by variofit.

output.reestimate logical. Only valid if reestimate = TRUE. Specifies whether the re-estimated parameters are returned.

locations.xvalid there are three possible specifications for this argument: "all" indicates the leaving-on-out method is used at all data locations. The second possibility is to use only a sub-set of the data for cross-validation in which case the argument takes a vector with numbers (indexes) indicating at which of the data locations the cross-validation should be performed. The third option is to perform external validation, on locations other than data locations used for the model. For the latter a matrix with the coordinates of the validation points should be provided and the argument data.xvalid mandatory.

data.xvalid data values at the validation locations. Only used if the validation locations are other than the data locations.

messages logical. Indicates whether status messages should be printed on the screen (or output device) while the function is running.

... further arguments to the minimization functions used by likfit, variofit.

Details

The cross-validation uses internally the function krig.conv to predict at each location.
For models fitted by `variofit` the parameters $\kappa, \psi_A, \psi_R$ and $\lambda$ are always regarded as fixed when reestimating the model.

See documentation of the function `likfit` for further details on the model specification and parameters.

**Value**

An object of the class "xvalid" which is a list with the following components:

- `data` the original data.
- `predicted` the values predicted by cross-validation.
- `krige.var` the cross-validation prediction variance.
- `error` the differences `data - predicted value`.
- `std.error` the errors divided by the square root of the prediction variances.
- `prob` the cumulative probability at original value under a normal distribution with parameters given by the cross-validation results.

A method for `summary` returns summary statistics for the errors and standard errors.

If `reestimate = TRUE` and `output = TRUE` additional columns are added to the resulting dataframe with the values of the re-estimated parameters.
