Package ‘micEcon’

March 17, 2017

Version 0.6-14
Date 2017-03-16
Title Microeconomic Analysis and Modelling
Author Arne Henningsen
Maintainer Arne Henningsen <arne.henningsen@gmail.com>
Depends R (>= 2.4.0)
Imports miscTools (>= 0.6-1), plm (>= 1.1-0)
Suggests Ecdat (>= 0.1-5), systemfit (>= 1.0-0)
Description Various tools for microeconomic analysis and microeconomic modelling, e.g. estimating quadratic, Cobb-Douglas and Translog functions, calculating partial derivatives and elasticities of these functions, and calculating Hessian matrices, checking curvature and preparing restrictions for imposing monotonicity of Translog functions.

Data on French Apple Producers in 1986

Description

The `appleProdFr86` data frame includes cross-sectional production data of 140 French apple producers from the year 1986. These data have been extracted from a panel data set that was used in Ivaldi et al. (1996).

Usage

`data(appleProdFr86)`

Format

This data frame contains the following columns:

- `vCap` costs of capital (including land).
- `vLab` costs of labour (including remuneration of unpaid family labour).
- `vMat` costs of intermediate materials (e.g. seedlings, fertilizer, pesticides, fuel).
- `qApples` quantity index of produced apples.
- `qOtherOut` quantity index of all other outputs.
- `qOut` quantity index of all outputs (not in the original data set, calculated as $580,000 \cdot (q_{Apples} + q_{OtherOut})$).
- `pCap` price index of capital goods.
**pLab** price index of labour.
**pMat** price index of materials.
**pOut** price index of the aggregate output (not in the original data set, artificially generated).
**adv** dummy variable indicating the use of an advisory service (not in the original data set, artificially generated).

**Source**

**References**

---

**Description**

The `bleymueller79E25.1` data frame contains prices and quantities of 4 products for the years 1970, 1974 and 1978. This data are part of Exercise 25.1 of Bleymueller, Gehler und Guetlicher (1979).

**Usage**

`data(bleymueller79E25.1)`

**Format**

This data frame contains the following columns:

- **p.A** Price of good A.
- **p.B** Price of good B.
- **p.C** Price of good C.
- **p.D** Price of good D.
- **q.A** Quantity of good A.
- **q.B** Quantity of good B.
- **q.C** Quantity of good C.
- **q.D** Quantity of good D.

**Source**

**checkConsist**  
*Testing Theoretical Consistency*

**Description**
Test theoretical consistency of microeconomic models.

**Usage**
```
checkConsist(object, ...)
```

**Arguments**
- `object`  a microeconomic model
- `...`  further arguments for methods

**Details**
This is a generic function.

**Author(s)**
Arne Henningsen

**See Also**
- `checkConsist.aidsEst`

**cobbDouglasCalc**  
*Calculate dependent variable of a Cobb-Douglas function*

**Description**
Calculate the dependent variable of a Cobb-Douglas function.

**Usage**
```
cobbDouglasCalc(xNames, data, coef, coefCov = NULL, dataLogged = FALSE)
```
**Arguments**

- **xNames**
  a vector of strings containing the names of the independent variables.
- **data**
  data frame containing the data.
- **coef**
  vector containing the coefficients: if the elements of the vector have no names, the first element is taken as intercept of the *logged* equation and the following elements are taken as coefficients of the independent variables defined in argument xNames (in the same order); if the elements of coef have names, the element named a0 is taken as intercept of the *logged* equation and the elements named a1,...,an are taken as coefficients of the independent variables defined in argument xNames (numbered in that order).
- **coefCov**
  optional covariance matrix of the coefficients (the order of the rows and columns must correspond to the order of the coefficients in argument coef).
- **dataLogged**
  logical. Are the values in data already logged?

**Value**

A vector containing the endogenous variable. If the inputs are provided as logarithmic values (argument dataLogged is TRUE), the endogenous variable is returned as logarithm; non-logarithmic values are returned otherwise.

If argument coefCov is specified, the returned vector has an attribute "variance" that is a vector containing the variances of the calculated (fitted) endogenous variable.

**Author(s)**

Arne Henningsen

**See Also**

- **translogCalc**, **cobbDouglasOpt**.

**Examples**

data( germanFarms )
# output quantity:
germanFarms$qOutput <- germanFarms$vOutput / germanFarms$pOutput
# quantity of variable inputs
germanFarms$qVarInput <- germanFarms$vVarInput / germanFarms$pVarInput
# a time trend to account for technical progress:
germanFarms$time <- c(1:20)

# estimate a Cobb-Douglas production function
estResult <- translogEst( "qOutput", c( "qLabor", "land", "qVarInput", "time" ),
    germanFarms, linear = TRUE )

# fitted values
fitted <- cobbDouglasCalc( c( "qLabor", "land", "qVarInput", "time" ), germanFarms,
    coef(estResult)[1:5] )
#equal to estResult$fitted
cobbDouglasDeriv

Derivatives of a Cobb-Douglas function

Description

Calculate the derivatives of a Cobb-Douglas function.

Usage

cobbDouglasDeriv( xNames, data, coef, coefCov = NULL, 
yName = NULL, dataLogged = FALSE )

Arguments

xNames           a vector of strings containing the names of the independent variables.
data             data frame containing the data.
coef             vector containing the coefficients: if the elements of the vector have no names, the first element is taken as intercept of the logged equation and the following elements are taken as coefficients of the independent variables defined in argument xNames (in the same order); if the elements of coef have names, the element named a_0 is taken as intercept of the logged equation and the elements named a_1,...,a_n are taken as coefficients of the independent variables defined in argument xNames (numbered in that order).
coefCov          optional covariance matrix of the coefficients (the order of the rows and columns must correspond to the order of the coefficients in argument coef).
yName            an optional string containing the name of the dependent variable. If it is NULL, the dependent variable is calculated from the independent variables and the coefficients.
dataLogged        logical. Are the values in data already logged?

Value

a list of class cobbDouglasDeriv containing following objects:
deriv             data frame containing the derivatives.
variance          data frame containing the variances of the derivatives (only if argument coefCov is provided). NOTE: if argument yName is specified, the variance of the endogenous variable is currently ignored.

margProductsObs$deriv
# t-values
margProductsObs$deriv / margProductsObs$variance^0.5

---

**cobbDouglasOpt**

**Optimal Values of Independent Variables of a Cobb-Douglas Function**

Description

Calculate the optimal values of the variable independent variables of a Cobb-Douglas function.

Usage

cobbDouglasOpt( pyName, pxNames, data, coef,
               zNames = NULL, zCoef = NULL, xNames = NULL, dataLogged = FALSE )
Arguments

- `pyName` character string containing the name of the price of the dependent variable.
- `pxNames` a vector of strings containing the names of the prices of the variable independent variables.
- `data` data frame containing the data.
- `coef` vector containing the intercept and the coefficients of the variable independent variables: if the elements of the vector have no names, the first element is taken as intercept of the logged equation and the following elements are taken as coefficients of the variable independent variables with corresponding prices defined in argument `pxNames` (in the same order); if the elements of `coef` have names, the element named `a_0` is taken as intercept of the logged equation and the elements named `a_1`, ..., `a_n` are taken as coefficients of the variable independent variables with corresponding prices defined in argument `xNames` (numbered in that order).
- `zNames` optional vector of strings containing the names of the fixed independent variables.
- `zCoef` vector containing the coefficients of the fixed independent variables: if the elements of the vector have no names, they are taken as coefficients of the fixed independent variables defined in argument `zNames` (in the same order); if the elements of `coef` have names, the elements named `d_1`, ..., `d_m` are taken as coefficients of the fixed independent variables with corresponding prices defined in argument `zNames` (numbered in that order).
- `xNames` optional vector of strings containing the names that should be assigned to the returned variable independent variables.
- `dataLogged` logical. Are the prices and fixed independent variables in `data` with names defined in `pyName`, `pxNames`, and `zNames` already logged?

Value

A data frame containing the optimal values of the variable independent variables. If the prices and fixed independent variables are provided as logarithmic values (argument `dataLogged` is `TRUE`), the optimal values of the variable independent variables are returned as logarithms, too; non-logarithmic values are returned otherwise.

**coef.quadFuncEst**

*Coefficients of a Quadratic Function*

**Description**

These methods return the coefficients and their covariance matrix from an estimated quadratic function.

**Usage**

```r
## S3 method for class 'quadFuncEst'
coef( object, ... )

## S3 method for class 'quadFuncEst'
vcov( object, ... )
```

**Arguments**

- `object`: an object of class quadFuncEst.
- `...`: currently ignored.

**Value**

The `coef` method returns a vector containing all (linearly independent) coefficients of a quadratic function.

The `vcov` method returns the covariance matrix of all (linearly independent) coefficients of a quadratic function.
Author(s)
Arne Henningsen

See Also
quadFuncEst

c coef.translogEst  Coefficients of a Translog Function

Description
These methods return the coefficients and their covariance matrix from an estimated translog function.

Usage

## S3 method for class 'translogEst'
coef( object, ... )

## S3 method for class 'translogEst'
v cov( object, ... )

Arguments

object  an object of class translogEst.

...  currently ignored.

Value

The coef method returns a vector containing all (linearly independent) coefficients of a translog function.

The v cov method returns the covariance matrix of all (linearly independent) coefficients of a translog function.

Author(s)

Arne Henningsen

translogEst
Calculating and returning elasticities

Description

These functions calculate and return elasticities of microeconomic models. `elasticities` is an alias for `elas`.

Usage

```
elas(object, ...)  
elasticities(object, ...)  
```

Details

This is a generic function. The default method just returns the element `elas` from `object`.

Author(s)

Arne Henningsen

`elas.aidsEst`

germanFarms

Output and Inputs of Farms in West-Germany

Description

The `germanFarms` data frame contains annual data of an average full-time farm in West-Germany. Additionally, the price indices for agricultural output and agricultural variable input are included. 20 book-keeping years are included - starting in 1975/76 and ending in 1994/95.

Usage

```
data(germanFarms)```
logDataSet

Format
This data frame contains the following columns:

- **year**: the book-keeping year.
- **vCrop**: the value of crop outputs (in current Deutschmark).
- **vAnimal**: the value of animal outputs (in current Deutschmark).
- **vOutput**: the value of outputs (in current Deutschmark).
- **pOutput**: price index of agricultural outputs (1980/81 = 100).
- **vVarInput**: the value of variable inputs (in current Deutschmark).
- **pVarInput**: price index of variable agricultural inputs (1980/81 = 100).
- **qLabor**: the number of full-time worker equivalents.
- **pLabor**: costs of an agricultural worker (Deutschmarks per year).
- **land**: land used for agricultural production (in ha).

Source

logDataSet
Creating a Data Set with the Logarithms of the Original Variables

Description
This function creates a data set with the logarithms of the original variables.

Usage
```r
logDataSet( data, varNames, varNamesNum = NULL )
```

Arguments
- **data**: a data frame containing the data (possibly a panel data frame created with `pdata.frame`).
- **varNames**: vector of character strings that indicates names of variables in the data frame. The logarithm of these variables are included in the returned data frame.
- **varNamesNum**: optional vector of character strings that indicates names of further variables in the data frame. In case of numeric variables, the logarithms of these variables are included in the returned data frame. In case of factor or logical variables, these variables are included in the returned data frame without any transformation.

Author(s)
Arne Henningsen
Examples

data( "germanFarms" )
datLog <- logDataSet( germanFarms, c( "vAnimal", "vOutput", "vVarInput" ) )
summary( datLog )

---

Missong03E7.7    Meat Prices and Quantities in Germany

Description

The Missong03E7.7 data frame contains meat prices and demanded quantities of a representative (West-)German household for the years 1986 to 1989. This data are part of Exercise 7.7 of Missong (2003).

Usage

data(Missong03E7.7)

Format

This data frame contains the following columns:

- **p.beef** Average price of beef (DM/kg).
- **q.beef** Demanded Quantity of beef (kg).
- **p.veal** Average price of veal (DM/kg).
- **q.veal** Demanded Quantity of veal (kg).
- **p.pork** Average price of pork (DM/kg).
- **q.pork** Demanded Quantity of pork (kg).

Source

### Description

Calculate the dependent variable of a quadratic function.

### Usage

```r
gwi <-- quadFunCalc( xNames, data, coef, shifternames = NULL, homWeights = NULL )
```

### Arguments

**xNames**
- a vector of strings containing the names of the independent variables.

**data**
- dataframe or a vector with named elements containing the data.

**coef**
- vector containing all coefficients: if there are \( n \) exogenous variables in `xNames` and \( m \) shifter variables in `shifternames`, the \( n+1 \) alpha coefficients must have names `a_0, ..., a_n`, the \( n(n+1)/2 \) beta coefficients must have names `b_1_1, ..., b_1_n, ..., b_n_n`, and the \( m \) delta coefficients must have names `d_1, ..., d_m` (only the elements of the upper right triangle of the beta matrix are directly obtained from `coef`; the elements of the lower left triangle are obtained by assuming symmetry of the beta matrix).

**shifternames**
- a vector of strings containing the names of the independent variables that should be included as shifters only (not in quadratic or interaction terms).

**homWeights**
- numeric vector with named elements that are weighting factors for calculating an index that is used to normalize the variables for imposing homogeneity of degree zero in these variables (see documentation of `quadFuncEst`).

### Value

- a vector containing the endogenous variable.

### Author(s)

Arne Henningsen

### See Also

- `quadFuncEst` and `quadFuncDeriv`
Examples

data( germanFarms )
# output quantity:
geermanFarms$qOutput <- germanFarms$vOutput / germanFarms$pOutput
# quantity of variable inputs
geermanFarms$qVarInput <- germanFarms$vVarInput / germanFarms$pVarInput
# a time trend to account for technical progress:
geermanFarms$time <- c(1:20)

# estimate a quadratic production function
estResult <- quadFuncEst( "qOutput", c( "qLabor", "land", "qVarInput", "time" ),
geermanFarms )

quadFuncCalc( c( "qLabor", "land", "qVarInput", "time" ), germanFarms,
coef( estResult ) )
#equal to estResult$fitted

quadFuncDeriv  Derivatives of a quadratic function

Description

Calculate the derivatives of a quadratic function.

Usage

quadFuncDeriv( xNames, data, coef, coefCov = NULL,
   homWeights = NULL )

Arguments

xNames       a vector of strings containing the names of the independent variables.
data           dataframe or a vector with named elements containing the data.
coef           vector containing all coefficients: if there are n exogenous variables in xNames,
               the n+1 alpha coefficients must have names a_0, ..., a_n and the n*(n+1)/2
               beta coefficients must have names b_1_1, ..., b_1_n, ..., b_n_n (only the
               elements of the upper right triangle of the beta matrix are directly obtained from
               coef; the elements of the lower left triangle are obtained by assuming symmetry
               of the beta matrix).
coefCov   optional covariance matrix of the coefficients: the row names and column names
         must be the same as the names of coef.
homWeights numeric vector with named elements that are weighting factors for calculating
         an index that is used to normalize the variables for imposing homogeneity of
         degree zero in these variables (see documentation of quadFuncEst).
Details

Shifter variables do not need to be specified, because they have no effect on the partial derivatives. Hence, you can use this function to calculate partial derivatives even for quadratic functions that have been estimated with shifter variables.

Value

A data frame containing the derivatives, where each column corresponds to one of the independent variables. If argument `coefCov` is provided, it has the attributes `variance` and `stdDev`, which are two data frames containing the variances and the standard deviations, respectively, of the derivatives.

quadFuncEla

Elasticities of a Quadratic Function

Description

Calculate elasticities of a quadratic function.
Usage
quadFuncEla( xNames, data, coef, yName = NULL, shifterNames = NULL, homWeights = NULL )

## S3 method for class 'quadFuncEst'
elas( object, data = NULL, yObs = FALSE, ... )

Arguments

- **xNames**: a vector of strings containing the names of the independent variables.
- **data**: dataframe or a vector with named elements containing the data; if argument data is not specified, the data frame that was used for the estimation is used for calculating elasticities.
- **coef**: vector containing all coefficients.
- **yName**: an optional string containing the name of the dependent variable. If it is NULL, the dependent variable is calculated from the independent variables and the coefficients.
- **shifterNames**: an optional vector of strings containing the names of the independent variables that are included as shifters only (not in quadratic or interaction terms).
- **homWeights**: numeric vector with named elements that are weighting factors for calculating an index that is used to normalize the variables for imposing homogeneity of degree zero in these variables (see documentation of `quadFuncEst`).
- **object**: object of class `quadFuncEst` (returned by `quadFuncEst`).
- **yObs**: logical. Use observed values of the endogenous variable. If FALSE (default) predicted values calculated by `quadFuncCalc` are used.
- **...**: currently ignored.

Value
A data.frame of class `quadFuncEla`, where each column corresponds to one of the independent variables.

Author(s)
Arne Henningsen

# output quantity:
germanFarms$qOutput <- germanFarms$vOutput / germanFarms$pOutput
# quantity of variable inputs
germanFarms$qVarInput <- germanFarms$vVarInput / germanFarms$pVarInput```
# a time trend to account for technical progress:
> germanFarms$time <- c(1:20)

# estimate a quadratic production function
> estResult <- quadFuncEst( yName = "qOutput",
> xNames = c( "qLabor", "land", "qVarInput", "time" ),
> data = germanFarms )

# compute the partial production elasticities with "fitted" output
> elaFit <- quadFuncEla( xNames = c( "qLabor", "land", "qVarInput", "time" ),
> data = germanFarms, coef = coef( estResult ) )
> elaFit

# same as
> elaFit2 <- elas( estResult )
> all.equal( elaFit, elaFit2 )

# compute the partial production elasticities with observed output
> elaObs <- quadFuncEla( xNames = c( "qLabor", "land", "qVarInput", "time" ),
> data = germanFarms, coef = coef( estResult ), yName = "qOutput" )
> elaObs

# same as
> elaObs2 <- elas( estResult, yObs = TRUE )
> all.equal( elaObs, elaObs2 )

---

**quadFuncEst**

*Estimate a quadratic function*

**Description**

Estimate a quadratic function.

**Usage**

```r
quadFuncEst( yName, xNames, data, shifterNames = NULL,
linear = FALSE, homWeights = NULL,
reg$Scale = 1, ... )
```

**Arguments**

- **yName**
  
a character string containing the name of the dependent variable.

- **xNames**
  
a vector of strings containing the names of the independent variables.

- **data**
  
data frame containing the data (possibly a panel data frame created with `pdata.frame`).

- **shifterNames**
  
a vector of strings containing the names of the independent variables that should be included as shifters only (not in quadratic or interaction terms).

- **linear**
  
logical. Restrict the coefficients of all quadratic and interaction terms to be zero so that the estimated function is linear in the exogenous variables?
homWeights numeric vector with named elements that are weighting factors for calculating an index that is used to normalize the variables for imposing homogeneity of degree zero in these variables (see details).

regScale a scalar or vector with length equal to nrow(data). All regressors except for shifter variables that are logical or factors are divided by regScale (NOTE: quadratic and interaction terms are also divided by regScale and NOT divided by the square of regScale).

... further arguments are passed to \texttt{lm} or \texttt{plm}.

Details

If argument homWeights is used to impose homogeneity of degree zero in some variables, the weighting factors in this vector must have names that are equal to the variable names in argument xNames. The order of the elements in homWeights is arbitrary and may or may not be equal to the order of the elements in xNames. Argument homWeights may contain less elements than xNames; in this case, homogeneity of degree zero is imposed only on variables with names in homWeights. Please note that the weighting factor of a variable \((P_i)\) in homWeights \((w_i = \partial P/\partial P_i)\) is not really its weight \(((\partial P/\partial P_i)(P_i/P))\), in particular, if the numerical values of the variables \((P_1,\ldots,P_n)\) are rather different.

Value

a list of class quadFuncEst containing following objects:

est \texttt{the object returned by lm or plm}.

nExog \texttt{length of argument xNames}.

nShifter \texttt{length of argument shifternames}.

residuals residuals.

fitted fitted values.

coef \texttt{vector of all coefficients}.

coefCov \texttt{covariance matrix of all coefficients}.

r2 \texttt{R}^2 \texttt{value}.

r2bar \texttt{adjusted R}^2 \texttt{value}.

nObs \texttt{number of observations}.

model.matrix \texttt{the model matrix}.

call \texttt{the matched call}.

yName \texttt{argument yName}.

xNames \texttt{argument xNames}.

shifternames \texttt{argument shifternames}.

homWeights \texttt{argument homWeights}.

regScale \texttt{argument regScale}.

cf residuals.translogEst  Residuals of a Translog function

Description
Extract the residuals from the estimation of a Translog function.

Usage
## S3 method for class 'translogEst'
residuals( object, ... )

Arguments

object an object of class translogEst.

... currently not used.

Value

residuals.translogEst returns a vector containing the residuals of an estimated translog function.

Author(s)

Arne Henningsen

translogEst and residuals
**summary.translogEst**  
*Summarizing the Estimation of a Translog Function*

**Description**

`summary.translogEst` summarizes the estimation results of a Translog Function.

**Usage**

```r
## S3 method for class 'translogEst'
summary(object, ...)

## S3 method for class 'summary.translogEst'
print(x, ...)
```

**Arguments**

- `object`: an object of class `translogEst`.
- `x`: an object of class `summary.translogEst`.
- `...`: currently ignored.

**Value**

`summary.translogEst` returns a list of class `summary.translogEst` that is currently the provided object, but an element `coefTable` has been added and the class has been changed.

**Author(s)**

Arne Henningsen

**See Also**

- `translogEst`.

---

**translogCalc**  
*Calculate dependent variable of a translog function*

**Description**

Calculate the dependent variable of a translog function.

**Usage**

```r
translogCalc(xNames, data, coef, shifterNames = NULL, dataLogged = FALSE)
```
Arguments

xNames a vector of strings containing the names of the independent variables.
data dataframe containing the data.
coef vector containing all coefficients: if there are n exogenous variables in xNames and m shifter variables in shifterNames, the n+1 alpha coefficients must have names a_0, ..., a_n, the n*(n+1)/2 beta coefficients must have names b_1_1, ..., b_1_n, ..., b_n_n, and the m delta coefficients must have names d_1, ..., d_m (only the elements of the upper right triangle of the beta matrix are directly obtained from coef; the elements of the lower left triangle are obtained by assuming symmetry of the beta matrix).
shifterNames a vector of strings containing the names of the independent variables that should be included as shifters only (not in quadratic or interaction terms).
dataLogged logical. Are the values in data already logged?

Value

A vector containing the endogenous variable. If the inputs are provided as logarithmic values (argument dataLogged is TRUE), the endogenous variable is returned as logarithm; non-logarithmic values are returned otherwise.

translogEst and translogDeriv.

Examples

data( germanFarms )
# output quantity:
germanFarms$qOutput <- germanFarms$vOutput / germanFarms$pOutput
# quantity of variable inputs
germanFarms$qVarInput <- germanFarms$vVarInput / germanFarms$pVarInput
# a time trend to account for technical progress:
germanFarms$time <- c(1:20)

# estimate a Translog production function
estResult <- translogEst( "qOutput", c( "qLabor", "land", "qVarInput", "time" ),
  germanFarms )
translogCalc( c( "qLabor", "land", "qVarInput", "time" ), germanFarms,
  coef( estResult ) )
#equal to estResult$fitted
translogCheckCurvature

Curvature of a Translog Function

Description

Check curvature of a translog function.

Usage

translogCheckCurvature( xNames, data, coef, convexity = TRUE, quasi = FALSE, dataLogged = FALSE, ... )

## S3 method for class 'translogCheckCurvature'
print( x, ... )

Arguments

- **xNames**: a vector of strings containing the names of the independent variables.
- **data**: dataframe containing the data.
- **coef**: vector containing all coefficients.
- **convexity**: logical. Check whether the function is (quasi)convex (default, TRUE) or (quasi)concave (FALSE).
- **quasi**: logical. Check whether the function is quasiconvex/quasiconcave (TRUE) or convex/concave (default, FALSE).
- **dataLogged**: logical. Are the values in data already logged?
- **x**: an object returned by translogCheckCurvature.
- **...**: arguments passed from translogCheckCurvature to semidefiniteness (if argument quasi is FALSE), quasiconvexity (if arguments convexity and quasi are both TRUE), or quasiconcavity (if argument convexity is FALSE and quasi is TRUE). Further arguments to print.translogCheckCurvature are currently ignored.

Value

translogCheckCurvature returns a list of class translogCheckCurvature containing following objects:

- **obs**: a vector indicating whether the condition for the specified curvature is fulfilled at each observation.
- **convexity**: argument convexity.
- **quasi**: argument quasi.

Arne Henningsen
translogCheckMono

See Also

`translogEst` and `translogCheckMono`

Examples

data( germanFarms )
# output quantity:
geermanFarms$qOutput <- germanFarms$vOutput / germanFarms$pOutput
# quantity of variable inputs
geermanFarms$qVarInput <- germanFarms$vVarInput / germanFarms$pVarInput
# a time trend to account for technical progress:
geermanFarms$time <- c(1:20)

# estimate a translog production function
estResult <- translogEst( "qOutput", c( "qLabor", "land", "qVarInput", "time" ),
geermanFarms )

# check whether the production function is quasiconcave
translogCheckCurvature( c( "qLabor", "land", "qVarInput", "time" ),
geermanFarms, coef( estResult ), convexity = FALSE, quasi = TRUE )

---

translogCheckMono  Monotonicity of a Translog Function

Description

Check monotonicity of a translog function.

Usage

translogCheckMono( xNames, data, coef, increasing = TRUE,
                   strict = FALSE, dataLogged = FALSE,
                   tol = 10 * .Machine$double.eps )

## S3 method for class 'translogCheckMono'
print( x, ... )

## S3 method for class 'translogCheckMono'
summary( object, ... )

## S3 method for class 'summary.translogCheckMono'
print( x, ... )

Arguments

- **xNames**: a vector of strings containing the names of the independent variables.
- **data**: dataframe containing the data.
- **coef**: vector containing all coefficients.
translogCheckMono

increasing  single logical value or vector of logical values of the same length as argument xNames indicating whether it should be checked if the translog function is monotonically increasing (default, TRUE) or decreasing (FALSE) in the explanatory variables.

strict  logical. Check for strict (TRUE) or non-strict (default, FALSE) monotonicity?
dataLogged  logical. Are the values in data already logged?
tol  tolerance level for checking non-strict monotonicity: values between -tol and tol are considered to be zero (ignored if argument strict is TRUE).
x  an object returned by translogCheckMono or by summary.translogCheckMono.
object  an object returned by translogCheckMono.
...  currently not used.

Details

Function translogCheckMono internally calls function translogDeriv and then checks if the derivatives have the sign specified in argument increasing.

Function translogCheckMono does not have an argument shifterNames, because shifter variables do not affect the monotonicity conditions of the explanatory variables defined in Argument xNames. Therefore, translogCheckMono automatically removes all coefficients of the shifter variables before it calls translogDeriv.

Value

translogCheckMono returns a list of class translogCheckMono containing following objects:

obs  a vector indicating whether monotonicity is fulfilled at each observation.
exog  data frame indicating whether monotonicity is fulfilled for each exogenous variable at each observation.
increasing  argument increasing.
strict  argument strict.

translogCostEst  Estimate a translog Cost Function

**Description**

Estimate a translog cost function.

NOTE: this function is still under development and incomplete!

**Usage**

```r
translogCostEst( cName, yName, pNames, data, fnames = NULL,
                 shifterNames = NULL, dataLogged = FALSE, homPrice = TRUE, ... )
```

**Arguments**

- **cName**: a string containing the name of the variable for total cost.
- **yName**: a string containing the name of the variable for the total output quantity.
- **pNames**: a vector of strings containing the names of the input prices.
- **data**: data frame containing the data (possibly a panel data frame created with `pdata.frame`).
- **fnames**: a vector of strings containing the names of fixed inputs.
- **shifterNames**: a vector of strings containing the names of the independent variables that should be included as shifters only (not in quadratic or interaction terms).
- **dataLogged**: logical. Are the values in data already logged?
- **homPrice**: logical. Should homogeneity of degree one in prices be imposed?
- **...**: further arguments are passed to `lm` or `plm`. 

---
translogCostEst

Value

a list of class translogCostEst containing following objects:

- est: the object returned by \texttt{lm} or \texttt{plm}.
- nExog: length of argument \texttt{xNames}.
- nShifter: length of argument \texttt{shifternames}.
- residuals: residuals.
- fitted: fitted values.
- coef: vector of all coefficients.
- coefCov: covariance matrix of all coefficients.
- r2: \( R^2 \) value.
- r2bar: adjusted \( R^2 \) value.
- nObs: number of observations.
- model.matrix: the model matrix.
- call: the matched call.
- cName: argument \texttt{cName}.
- yName: argument \texttt{yName}.
- pNames: argument \texttt{pNames}.
- fNames: argument \texttt{fNames}.
- shifternames: argument \texttt{shifternames}.
- dataLogged: argument \texttt{dataLogged}.
- homPrice: argument \texttt{homPrice}.

germanFarms$vLabor <- germanFarms$pLabor + germanFarms$qLabor
# total variable cost
germanFarms$cost <- germanFarms$vLabor + germanFarms$vVarInput
# a time trend to account for technical progress:
germanFarms$time <- c(1:20)

# estimate a translog cost function
translogDeriv

Derivatives of a translog function

Description

Calculate the derivatives of a translog function.

Usage

translogDeriv(xNames, data, coef, coefCov = NULL, yName = NULL, dataLogged = FALSE)

Arguments

xNames a vector of strings containing the names of the independent variables.
data dataframe containing the data.
coef vector containing all coefficients.
coefCov optional covariance matrix of the coefficients.
yName an optional string containing the name of the dependent variable. If it is NULL, the dependent variable is calculated from the independent variables and the coefficients.
dataLogged logical. Are the values in data already logged?

Value

a list of class translogDeriv containing following objects:
deriv data frame containing the derivatives.
variance data frame containing the variances of the derivatives (not implemented yet).
stdDev data frame containing the standard deviations of the derivatives (not implemented yet).

margProductsObs$deriv

translogEla Elasticities of a translog Function

Description

Calculate the elasticities of a translog function.

Usage

translogEla( xNames, data, coef, coefCov = NULL,
              dataLogged = FALSE )

## S3 method for class 'translogEst'
elas( object, data = NULL, dataLogged = NULL,
       ... )

Arguments

xNames a vector of strings containing the names of the independent variables.

data dataframe containing the data; if argument data of elas.translogEst is not specified, the data frame that was used for the estimation is used for calculating elasticities.

coef vector containing all coefficients: if there are n exogenous variables in xNames, the n+1 alpha coefficients must have names a_0, ..., a_n and the n*(n+1)/2
beta coefficients must have names $b_{1,1}, \ldots, b_{1,n}, \ldots, b_{n,n}$ (only the elements of the upper right triangle of the beta matrix are directly obtained from `coef`; the elements of the lower left triangle are obtained by assuming symmetry of the beta matrix).

`coefCov` optional covariance matrix of the coefficients: the row names and column names must be the same as the names of `coef`.

`dataLogged` logical. Are the values in `data` already logged? If argument `dataLogged` of `elas.translogEst` is not specified, the same value as used in `translogEst` for creating object is used.

`object` object of class `translogEst` (returned by `translogEst`).

Details

Shifter variables do not need to be specified, because they have no effect on the elasticities. Hence, you can use this function to calculate elasticities even for translog functions that have been estimated with shifter variables.

Value

A data frame containing the elasticities, where each column corresponds to one of the independent variables. If argument `coefCov` is provided, it has the attributes `variance` and `stddev`, which are two data frames containing the variances and the standard deviations, respectively, of the elasticities.

# a time trend to account for technical progress:
germanFarms$Time <- c(1:20)

# estimate a quadratic production function
estResult <- translogEst( "qOutput", c( "qLabor", "land", "qVarInput", "time" ),
    germanFarms )

# calculate production elasticities of all inputs
estEla <- translogEla( c( "qLabor", "land", "qVarInput", "time" ),
    data = germanFarms, coef = coef( estResult ),
    coefCov = vcov( estResult ) )
```
translogEst

# all elasticities
estEla
# t-values of all elasticities
estEla / attributes(estEla)$stdDev

describe

Estimate a translog function

Description
Estimate a translog function.

Usage
translogEst( yName, xNames, data, shifterNames = NULL,
dataLogged = FALSE, ... )

## S3 method for class 'translogEst'
print( x, ... )

Arguments

- `yName` a string containing the name of the dependent variable.
- `xNames` a vector of strings containing the names of the independent variables.
- `data` data frame containing the data (possibly a panel data frame created with `pdata.frame`).
- `shifterNames` a vector of strings containing the names of the independent variables that should be included as shifters only (not in quadratic or interaction terms).
- `dataLogged` logical. Are the values in data already logged? If FALSE, the logarithms of all variables (yName, xNames, shifterNames) are used except for shifter variables that are factors or logical variables.
- `x` An object of class translogEst.
- `...` further arguments of translogEst are passed to `lm` or `plm`; further arguments of print.translogEst are currently ignored.

Value
a list of class translogEst containing following objects:

- `est` the object returned by `lm` or `plm`.
- `nexog` length of argument xNames.
- `nShifter` length of argument shifterNames.
- `residuals` residuals.
- `fitted` fitted values.
- `coef` vector of all coefficients.
translogHessian

- **coefCov**: covariance matrix of all coefficients.
- **r2**: $R^2$ value.
- **r2bar**: adjusted $R^2$ value.
- **nObs**: number of observations.
- **model.matrix**: the model matrix.
- **call**: the matched call.
- **yName**: argument yName.
- **xNames**: argument xNames.
- **shifterNames**: argument shifterNames.
- **dataLogged**: argument dataLogged.

estResult
summary( estResult )
```

---

**translogHessian**

**Hessian matrix of a translog function**

**Description**

Calculate the Hessian matrices of a translog function.

**Usage**

```r
translogHessian( xNames, data, coef, yName = NULL,
dataLogged = FALSE, bordered = FALSE )
```
Arguments

- **xNames**: a vector of strings containing the names of the independent variables.
- **data**: dataframe containing the data.
- **coef**: vector containing all coefficients.
- **yName**: an optional string containing the name of the dependent variable. If it is NULL, the dependent variable is calculated from the independent variables and the coefficients.
- **dataLogged**: logical. Are the values in data already logged?
- **bordered**: logical. Should the bordered Hessians be returned?

Value

A list containing following the (bordered) Hessian matrices at each data point.

borderedHessians[[ 1 ]]]

translogMonoRestr  
Monotonicity Restrictions of a Translog Function

Description

Create matrix to check or impose the monotonicity restrictions of a translog function.

Usage

translogMonoRestr( xNames, data,
                  dataLogged = FALSE, box = FALSE )

Arguments

xNames  a vector of strings containing the names of the independent variables.
data    dataframe containing the data.
dataLogged logical. Are the values in data already logged?
box     logical. Should monotonicity be imposed within an \( n \)-dimensional box that includes all points in data? If FALSE, monotonicity is imposed (only) within an \( n \)-dimensional polygon that includes all points in data. (\( n \) is the number of independent variables.)

Value

translogMonoRestr returns a matrix of dimension \((n \cdot N) \times c\), where \( n \) is the number of independent variables, \( N \) is the number of data points at which monotonicity should be imposed (if argument box is FALSE, \( N \) is the number of rows in data; if argument box is TRUE, \( N = 2^n \)), and \( c = 1 + n(n + 3)/2 \) is the number of (linearly independent) coefficients. Multiplying a row of this matrix (e.g. the \( k \)th row of \( M \)) by the vector of coefficients (\( \beta \)) results in the derivative of the dependent variable (\( y \)) with respect to one independent variable (e.g. \( x_i \)) at one data point (e.g. \( j \)):

\[
M[k,] \cdot \beta = \frac{\partial \ln y}{\partial \ln x_i}
\]

, evaluated at \( x_{1j}, \ldots, x_{nj} \), where \( k = (i - 1)N + j \). Hence, the observations run faster than the independent variables.

translogProdFuncMargCost

Marginal Costs of Translog Production Function

Description

Calculate the marginal costs of the output from a translog production function.

Usage

translogProdFuncMargCost( yName, xNames, wNames, data, coef, dataLogged = FALSE )

Arguments

yName a single character string containing the name of the output quantity.
xNames a vector of strings containing the names of the input quantities.
wNames a vector of strings containing the names of the input prices.
data dataframe containing the data.
coef vector containing all coefficients: if there are n inputs in xNames, the n+1 alpha coefficients must have names a_0, ..., a_n and the n*(n+1)/2 beta coefficients must have names b_1_1, ..., b_1_n, ..., b_n_n (only the elements of the upper right triangle of the beta matrix are directly obtained from coef; the elements of the lower left triangle are obtained by assuming symmetry of the beta matrix).
dataLogged logical. Are the values in data already logged?

Value

A vector containing the marginal costs of producing the output.
