accumulate

Accumulate intermediate results of a vector reduction

Description

accumulate() sequentially applies a 2-argument function to elements of a vector. Each application of the function uses the initial value or result of the previous application as the first argument. The second argument is the next value of the vector. The results of each application are returned in a list. The accumulation can optionally terminate before processing the whole vector in response to a done() signal returned by the accumulation function.

By contrast to accumulate(), reduce() applies a 2-argument function in the same way, but discards all results except that of the final function application.

accumulate2() sequentially applies a function to elements of two lists, .x and .y.
accumulate

Usage

accumulate(.x, .f, ..., .init, .dir = c("forward", "backward"))

accumulate2(.x, .y, .f, ..., .init)

Arguments

.x A list or atomic vector.

.f For accumulate() .f is 2-argument function. The function will be passed the accumulated result or initial value as the first argument. The next value in sequence is passed as the second argument.

For accumulate2(), a 3-argument function. The function will be passed the accumulated result as the first argument. The next value in sequence from .x is passed as the second argument. The next value in sequence from .y is passed as the third argument.

The accumulation terminates early if .f returns a value wrapped in a done().

... Additional arguments passed on to the mapped function.

.init If supplied, will be used as the first value to start the accumulation, rather than using .x[[1]]. This is useful if you want to ensure that reduce returns a correct value when .x is empty. If missing, and .x is empty, will throw an error.

.dir The direction of accumulation as a string, one of "forward" (the default) or "backward". See the section about direction below.

.y For accumulate2() .y is the second argument of the pair. It needs to be 1 element shorter than the vector to be accumulated (.x). If .init is set, .y needs to be one element shorter than the concatenation of the initial value and .x.

Value

A vector the same length of .x with the same names as .x.

If .init is supplied, the length is extended by 1. If .x has names, the initial value is given the name ".init", otherwise the returned vector is kept unnamed.

If .dir is "forward" (the default), the first element is the initial value (.init if supplied, or the first element of .x) and the last element is the final reduced value. In case of a right accumulation, this order is reversed.

The accumulation terminates early if .f returns a value wrapped in a done(). If the done box is empty, the last value is used instead and the result is one element shorter (but always includes the initial value, even when terminating at the first iteration).

Life cycle

accumulate_right() is soft-deprecated in favour of the .dir argument as of rlang 0.3.0. Note that the algorithm has slightly changed: the accumulated value is passed to the right rather than the left, which is consistent with a right reduction.

Direction

When .f is an associative operation like + or c(), the direction of reduction does not matter. For instance, reducing the vector 1:3 with the binary function + computes the sum ((1 + 2) + 3) from the left, and the same sum (1 + (2 + 3)) from the right.
In other cases, the direction has important consequences on the reduced value. For instance, reducing a vector with `list()` from the left produces a left-leaning nested list (or tree), while reducing `list()` from the right produces a right-leaning list.

**See Also**

`reduce()` when you only need the final reduced value.

**Examples**

```r
# With an associative operation, the final value is always the same, no matter the direction. You’ll find it in the last element for a backward (left) accumulation, and in the first element for forward (right) one:

1:5 %>% accumulate(""+")
1:5 %>% accumulate("+", .dir = "backward")

# The final value is always equal to the equivalent reduction:

1:5 %>% reduce("+")

# It is easier to understand the details of the reduction with 'paste()'.

accumulate(letters[1:5], paste, sep = ".")

# Note how the intermediary reduced values are passed to the left with a left reduction, and to the right otherwise:

accumulate(letters[1:5], paste, sep = ".", .dir = "backward")

# `accumulate2()` is a version of `accumulate()` that works with 3-argument functions and one additional vector:

paste2 <- function(x, y, sep = ".") paste(x, y, sep = sep)
letters[1:4] %>% accumulate(paste2)
letters[1:4] %>% accumulate2(c("-", ".", "-"), paste2)

# You can shortcircuit an accumulation and terminate it early by returning a value wrapped in a `done()`. In the following example we return early if the result-so-far, which is passed on the LHS, meets a condition:

paste3 <- function(out, input, sep = ".") {
  if (nchar(out) > 4) {
    return(done(out))
  }
  paste(out, input, sep = sep)
}

letters %>% accumulate(paste3)

# Note how we get twice the same value in the accumulation. That’s because we have returned it twice. To prevent this, return an empty done box to signal to `accumulate()` that it should terminate with the value of the last iteration:

paste3 <- function(out, input, sep = ".") {
  if (nchar(out) > 4) {
    return(done())
  }
  paste(out, input, sep = sep)
}
array-coercion

letters %>% accumulate(paste3)

# Here the early return branch checks the incoming inputs passed on
# the RHS:
paste4 <- function(out, input, sep = ".") {
  if (input == "f") {
    return(done())
  }
  paste(out, input, sep = sep)
}
letters %>% accumulate(paste4)

# Simulating stochastic processes with drift
## Not run:
library(dplyr)
library(ggplot2)

rerun(5, rnorm(100)) %>%
  set_names(paste0("sim", 1:5)) %>%
  map(~ accumulate(., ~ .05 + .x + .y)) %>%
  map_dfr(~ tibble(value = .x, step = 1:100), .id = "simulation") %>%
  ggplot(aes(x = step, y = value)) +
  geom_line(aes(color = simulation)) +
  ggtitle("Simulations of a random walk with drift")
## End(Not run)

array-coercion

Coerce array to list

Description

array_branch() and array_tree() enable arrays to be used with purrr’s functionals by turning them into lists. The details of the coercion are controlled by the margin argument. array_tree() creates an hierarchical list (a tree) that has as many levels as dimensions specified in margin, while array_branch() creates a flat list (by analogy, a branch) along all mentioned dimensions.

Usage

array_branch(array, margin = NULL)
array_tree(array, margin = NULL)

Arguments

array An array to coerce into a list.
margin A numeric vector indicating the positions of the indices to be to be enlisted. If NULL, a full margin is used. If numeric(0), the array as a whole is wrapped in a list.
Details

When no margin is specified, all dimensions are used by default. When margin is a numeric vector of length zero, the whole array is wrapped in a list.

Examples

# We create an array with 3 dimensions
x <- array(1:12, c(2, 2, 3))

# A full margin for such an array would be the vector 1:3. This is
# the default if you don’t specify a margin

# Creating a branch along the full margin is equivalent to
# as.list(array) and produces a list of size length(x):
array_branch(x) %>% str()

# A branch along the first dimension yields a list of length 2
# with each element containing a 2x3 array:
array_branch(x, 1) %>% str()

# A branch along the first and third dimensions yields a list of
# length 2x3 whose elements contain a vector of length 2:
array_branch(x, c(1, 3)) %>% str()

# Creating a tree from the full margin creates a list of lists of
# lists:
array_tree(x) %>% str()

# The ordering and the depth of the tree are controlled by the
# margin argument:
array_tree(x, c(3, 1)) %>% str()

---

as_mapper

Convert an object into a mapper function

Description

as_mapper is the powerhouse behind the varied function specifications that most purrr functions allow. It is an S3 generic. The default method forwards its arguments to rlang::as_function().

Usage

as_mapper(.f, ...)

## S3 method for class 'character'
as_mapper(.f, ..., .null, .default = NULL)

## S3 method for class 'numeric'
as_mapper(.f, ..., .null, .default = NULL)

## S3 method for class 'list'
as_mapper(.f, ..., .null, .default = NULL)
as_vector

Arguments

.f A function, formula, or vector (not necessarily atomic).
If a function, it is used as is.
If a formula, e.g. ~ .x + 2, it is converted to a function. There are three ways
to refer to the arguments:
  • For a single argument function, use .
  • For a two argument function, use .x and .y
  • For more arguments, use ..1, ..2, ..3 etc
This syntax allows you to create very compact anonymous functions.
If character vector, numeric vector, or list, it is converted to an extractor func-
tion. Character vectors index by name and numeric vectors index by position;
use a list to index by position and name at different levels. If a component is not
present, the value of .default will be returned.

... Additional arguments passed on to methods.

.default, .null
Optional additional argument for extractor functions (i.e. when .f is character,
integer, or list). Returned when value is absent (does not exist) or empty (has
length 0). .null is deprecated; please use .default instead.

Examples

as_mapper(~ . + 1)
as_mapper()

as_mapper(c("a", "b", "c"))
# Equivalent to function(x) x["a"][["b"]]["c"]

as_mapper(list(1, "a", 2))
# Equivalent to function(x) x[[1]]["a"][2]

as_mapper(list(1, attr_getter("a")))
# Equivalent to function(x) attr(x[[1]], "a")

as_mapper(c("a", "b", "c"), .null = NA)

as_vector

Coerce a list to a vector

Description

as_vector() collapses a list of vectors into one vector. It checks that the type of each vector is
consistent with .type. If the list can not be simplified, it throws an error. simplify will simplify a
vector if possible; simplify_all will apply simplify to every element of a list.

Usage

as_vector(.x, .type = NULL)
simplify(.x, .type = NULL)
simplify_all(.x, .type = NULL)
attr_getter

Create an attribute getter function

Description

attr_getter() generates an attribute accessor function; i.e., it generates a function for extracting an attribute with a given name. Unlike the base R attr() function with default options, it doesn’t use partial matching.

Usage

attr_getter(attr)

Arguments

attr

An attribute name as string.

See Also

pluck()
Examples

# attr_getter() takes an attribute name and returns a function to
# access the attribute:
get_rownames <- attr_getter("row.names")
get_rownames(mtcars)

# These getter functions are handy in conjunction with pluck() for
# extracting deeply into a data structure. Here we'll first
# extract by position, then by attribute:
obj1 <- structure("obj", obj_attr = "foo")
obj2 <- structure("obj", obj_attr = "bar")
x <- list(obj1, obj2)

pluck(x, 1, attr_getter("obj_attr"))  # From first object
pluck(x, 2, attr_getter("obj_attr"))  # From second object

compose
Compose multiple functions

Description
Compose multiple functions

Usage
compose(..., .dir = c("backward", "forward"))

Arguments
...
Functions to apply in order (from right to left by default). Formulas are con-
verted to functions in the usual way. These dots support tidy dots features. In particular, if your functions are stored
in a list, you can splice that in with !!!.

[dir]
If "backward" (the default), the functions are called in the reverse order, from
right to left, as is conventional in mathematics. If "forward", they are called
from left to right.

Value
A function

Examples
not_null <- compose(`!`, is.null)
not_null(4)
not_null(NULL)

add1 <- function(x) x + 1
compose(add1, add1)(8)

# You can use the formula shortcut for functions:
fn <- compose(~ paste(.x, "foo"), ~ paste(.x, "bar"))
fn("input")
# Lists of functions can be spliced with `!!!`

```r
fns <- list(
  function(x) paste(x, "foo"),
  ~ paste(.x, "bar")
)
fn <- compose(!!!fns)
fn("input")
```

## Cross

### Produce all combinations of list elements

**Description**

cross2() returns the product set of the elements of `.x` and `.y`. cross3() takes an additional `.z` argument. cross() takes a list `.l` and returns the cartesian product of all its elements in a list, with one combination by element. cross_df() is like cross() but returns a data frame, with one combination by row.

### Usage

```r
cross(.l, .filter = NULL)
cross2(.x, .y, .filter = NULL)
cross3(.x, .y, .z, .filter = NULL)
cross_df(.l, .filter = NULL)
```

### Arguments

- `.l` A list of lists or atomic vectors. Alternatively, a data frame. cross_df() requires all elements to be named.
- `.filter` A predicate function that takes the same number of arguments as the number of variables to be combined.
- `.x`, `.y`, `.z` Lists or atomic vectors.

### Details

cross(), cross2() and cross3() return the cartesian product is returned in wide format. This makes it more amenable to mapping operations. cross_df() returns the output in long format just as expand.grid() does. This is adapted to rowwise operations.

When the number of combinations is large and the individual elements are heavy memory-wise, it is often useful to filter unwanted combinations on the fly with `.filter`. It must be a predicate function that takes the same number of arguments as the number of crossed objects (2 for cross2(), 3 for cross3(), length(.l) for cross()) and returns TRUE or FALSE. The combinations where the predicate function returns TRUE will be removed from the result.

### Value

cross2(), cross3() and cross() always return a list. cross_df() always returns a data frame. cross() returns a list where each element is one combination so that the list can be directly mapped over. cross_df() returns a data frame where each row is one combination.
cross

See Also

expand.grid()

Examples

# We build all combinations of names, greetings and separators from our
# list of data and pass each one to paste()
data <- list(
  id = c("John", "Jane"),
  greeting = c("Hello.", "Bonjour."),
  sep = c("! ", "... ")
)
data %>%
cross() %>%
map(lift(paste))

# cross() returns the combinations in long format: many elements,
# each representing one combination. With cross_df() we’ll get a
# data frame in long format: crossing three objects produces a data
# frame of three columns with each row being a particular
# combination. This is the same format that expand.grid() returns.
args <- data %>% cross_df()

# In case you need a list in long format (and not a data frame)
# just run as.list() after cross_df()
args %>% as.list()

# This format is often less practical for functional programming
# because applying a function to the combinations requires a loop
out <- vector("list", length = nrow(args))
for (i in seq_along(out))
  out[[i]] <- map(args, i) %>% invoke(paste, .)
out

# It’s easier to transpose and then use invoke_map()
args %>% transpose() %>% map_chr(~ invoke(paste, .))

# Unwanted combinations can be filtered out with a predicate function
filter <- function(x, y) x >= y
cross2(1:5, 1:5, .filter = filter) %>% str()

# To give names to the components of the combinations, we map
# setNames() on the product:
seq_len(3) %>%
cross2(., ., .filter = `==`) %>%
map(setNames, c("x", "y"))

# Alternatively we can encapsulate the arguments in a named list
# before crossing to get named components:
seq_len(3) %>%
list(x = ., y = .) %>%
cross(.filter = `==`)
detect

Find the value or position of the first match

Description
Find the value or position of the first match

Usage
detect(.x, .f, ..., .dir = c("forward", "backward"), .right = NULL, .default = NULL)
detect_index(.x, .f, ..., .dir = c("forward", "backward"), .right = NULL)

Arguments
.x A list or atomic vector.
.f A function, formula, or vector (not necessarily atomic).
If a function, it is used as is.
If a formula, e.g. ~ .x + 2, it is converted to a function. There are three ways to refer to the arguments:
• For a single argument function, use .
• For a two argument function, use .x and .y
• For more arguments, use ..1, ..2, ..3 etc
This syntax allows you to create very compact anonymous functions.
If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of .default will be returned.
...
Additional arguments passed on to .p.
.dir If "forward", the default, starts at the beginning of the vector and move towards the end; if "backward", starts at the end of the vector and moves towards the beginning.
.right Soft-deprecated. Please use .dir instead.
.default The value returned when nothing is detected.

Value
detect the value of the first item that matches the predicate; detect_index the position of the matching item. If not found, detect returns NULL and detect_index returns 0.

See Also
keep() for keeping all matching values.
### Examples

is_even <- function(x) x %% 2 == 0

3:10 %>% detect(is_even)
3:10 %>% detect_index(is_even)

3:10 %>% detect(is_even, .right = TRUE)
3:10 %>% detect_index(is_even, .right = TRUE)

# Since `.f` is passed to as_mapper(), you can supply a
# lambda-formula or a pluck object:
x <- list(
  list(1, foo = FALSE),
  list(2, foo = TRUE),
  list(3, foo = TRUE)
)

detect(x, "foo")
detect_index(x, "foo")

# If you need to find all values, use keep():
keep(x, "foo")

# If you need to find all positions, use map_lgl():
which(map_lgl(x, "foo"))

---

### Description

These objects are imported from other packages. Follow the links below to see their documentation.

- **rlang**

---

### every

**Do every or some elements of a list satisfy a predicate?**

**Description**

Do every or some elements of a list satisfy a predicate?

**Usage**

- every(.x, .p, ...)
- some(.x, .p, ...)
Arguments

\.x\ A list or atomic vector.
\.p\ A predicate function to apply on each element of \.x. \texttt{some()} returns \texttt{TRUE} when \.p is \texttt{TRUE} for at least one element. \texttt{every()} returns \texttt{TRUE} when \.p is \texttt{TRUE} for all elements.

... Additional arguments passed on to \.p.

Value

A logical vector of length 1.

Examples

\begin{verbatim}
y <- list(0:10, 5.5)
y %>% every(is.numeric)
y %>% every(is.integer)
\end{verbatim}

Description

These objects are imported from other packages. Follow the links below to see their documentation.

\textbf{rlang} exec

| flatten
| Flatten a list of lists into a simple vector.

Description

These functions remove a level hierarchy from a list. They are similar to \texttt{unlist()}, but they only ever remove a single layer of hierarchy and they are type-stable, so you always know what the type of the output is.

Usage

\begin{verbatim}
flatten(.x)
flatten_lgl(.x)
flatten_int(.x)
flatten_dbl(.x)
flatten_chr(.x)
flatten_raw(.x)
flatten_dfr(.x, .id = NULL)
flatten_dfc(.x)
\end{verbatim}
**has_element**

**Description**

Does a list contain an object?

**Usage**

has_element(.x, .y)

**Arguments**

- **.x** A list or atomic vector.
- **.y** Object to test for

**Examples**

```r
x <- list(1:10, 5, 9.9)
x %>% has_element(1:10)
x %>% has_element(3)
```
head_while

*Find head/tail that all satisfies a predicate.*

**Description**

Find head/tail that all satisfies a predicate.

**Usage**

```r
head_while(.x, .p, ...)
tail_while(.x, .p, ...)
```

**Arguments**

- **.x**: A list or atomic vector.
- **.p**: A single predicate function, a formula describing such a predicate function, or a logical vector of the same length as .x. Alternatively, if the elements of .x are themselves lists of objects, a string indicating the name of a logical element in the inner lists. Only those elements where .p evaluates to TRUE will be modified.
- **...**: Additional arguments passed on to the mapped function.

**Value**

A vector the same type as .x.

**Examples**

```r
pos <- function(x) x >= 0
head_while(5:-5, pos)
tail_while(5:-5, negate(pos))

big <- function(x) x > 100
head_while(0:10, big)
tail_while(0:10, big)
```

imap

*Apply a function to each element of a vector, and its index*

**Description**

imap_XXX(x, ...), an indexed map, is short hand for `map2(x, names(x), ...) if x has names, or map2(x, seq_along(x), ...)` if it does not. This is useful if you need to compute on both the value and the position of an element.
**imap**

**Usage**

imap(.x, .f, ...)
imap_lgl(.x, .f, ...)
imap_chr(.x, .f, ...)
imap_int(.x, .f, ...)
imap_dbl(.x, .f, ...)
imap_raw(.x, .f, ...)
imap_dfr(.x, .f, ..., .id = NULL)
imap_dfc(.x, .f, ...)
iwalk(.x, .f, ...)

**Arguments**

.x A list or atomic vector.
.f A function, formula, or vector (not necessarily atomic).
If a function, it is used as is.
If a formula, e.g. ~ .x + 2, it is converted to a function. There are three ways to refer to the arguments:
• For a single argument function, use .
• For a two argument function, use .x and .y
• For more arguments, use ..1, ..2, ..3 etc
This syntax allows you to create very compact anonymous functions.
If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of .default will be returned.
...
... Additional arguments passed on to the mapped function.
.id Either a string or NULL. If a string, the output will contain a variable with that name, storing either the name (if .x is named) or the index (if .x is unnamed) of the input. If NULL, the default, no variable will be created.
Only applies to _dfr variant.

**Value**

A vector the same length as .x.

**See Also**

Other map variants: invoke, lmap, map2, map, modify
Examples

# Note that when using the formula shortcut, the first argument
# is the value, and the second is the position
imap_chr(sample(10), ~ paste0(.y, ": ", .x))
iwalk(mtcars, ~ cat(.y, ": ", median(.x), 
\n", sep = ""))

insistently

Transform a function to make it run insistently or slowly

Description

- insistently() takes a function and modifies it to retry a given amount of time on error.
- slowly() takes a function and modifies it to wait a given amount of time between each call.

The number and rate of attempts is determined by a rate object (by default a jittered exponential backoff rate for insistently(), and a constant rate for slowly()).

Usage

insistently(f, rate = rate_backoff(), quiet = TRUE)
slowly(f, rate = rate_delay(), quiet = TRUE)

Arguments

f A function to modify.
rate A rate object determining the waiting time.
quiet If FALSE, prints a message displaying how long until the next request.

See Also

httr::RETRY() is a special case of insistently() for HTTP verbs. rate_backoff() and rate_delay() for creating custom backoff rates. rate_sleep() for the function powering insistently() and slowly(). safely() for another useful function operator.

Examples

# For the purpose of this example, we first create a custom rate
# object with a low waiting time between attempts:
rate <- rate_delay(0.1)

# slowly() causes a function to sleep for a given time between calls:
slow_runif <- slowly(~ runif(1), rate = rate, quiet = FALSE)
map(1:5, slow_runif)

# insistently() makes a function repeatedly try to work
risky_runif <- function(lo = 0, hi = 1) {
y <- runif(1, lo, hi)
if(y < 0.9) {
  stop(y, " is too small")
}
# Let's now create an exponential backoff rate with a low waiting time between attempts:
rate <- rate_backoff(pause_base = 0.1, pause_min = 0.005, max_times = 4)

# Modify your function to run insistently.
insistent_risky_runif <- insistently(risky_runif, rate, quiet = FALSE)

set.seed(6) # Succeeding seed
insistent_risky_runif()

set.seed(3) # Failing seed
try(insistent_risky_runif())

# You can also use other types of rate settings, like a delay rate that waits for a fixed amount of time. Be aware that a delay rate has an infinite amount of attempts by default:
rate <- rate_delay(0.2, max_times = 3)
insistent_risky_runif <- insistently(risky_runif, rate = rate, quiet = FALSE)
try(insistent_risky_runif())

# insistently() and possibly() are a useful combination
rate <- rate_backoff(pause_base = 0.1, pause_min = 0.005)
possibly_insistent_risky_runif <- possibly(insistent_risky_runif, otherwise = -99)

set.seed(6)
possibly_insistent_risky_runif()

set.seed(3)
possibly_insistent_risky_runif()

---

**keep**

*Keep or discard elements using a predicate function.*

**Description**

*keep()* and *discard()* are opposites. *compact()* is a handy wrapper that removes all empty elements.

**Usage**

```r
keep(.x, .p, ...)

discard(.x, .p, ...)

compact(.x, .p = identity)
```
Arguments

.x A list or vector.
.p For keep() and discard(), a predicate function. Only those elements where .p evaluates to TRUE will be kept or discarded.
For compact(), a function that is applied to each element of .x. Only those elements where .p evaluates to an empty vector will be discarded.

... Additional arguments passed on to .p.

Details

These are usually called select or filter and reject or drop, but those names are already taken. keep() is similar to Filter(), but the argument order is more convenient, and the evaluation of the predicate function .p is stricter.

Examples

```r
rep(10, 10) %>%
  map(sample, 5) %>%
  keep(function(x) mean(x) > 6)
```

# Or use a formula
```r
rep(10, 10) %>%
  map(sample, 5) %>%
  keep(~ mean(.x) > 6)
```

# Using a string instead of a function will select all list elements
# where that subelement is TRUE
```r
x <- rerun(5, a = rbernoulli(1), b = sample(10))
x
x %>% keep("a")
x %>% discard("a")
```

# compact() discards elements that are NULL or that have length zero
```r
list(a = "a", b = NULL, c = integer(0), d = NA, e = list()) %>%
  compact()
```

lift

Lift the domain of a function

Description

lift_xy() is a composition helper. It helps you compose functions by lifting their domain from a kind of input to another kind. The domain can be changed from and to a list (l), a vector (v) and dots (d). For example, lift_ld(fun) transforms a function taking a list to a function taking dots.

Usage

lift(.f, ..., .unnamed = FALSE)

lift_dl(.f, ..., .unnamed = FALSE)

lift_dv(.f, ..., .unnamed = FALSE)
lift_vl(..f, ..., .type)
lift_vd(..f, ..., .type)
lift_ld(..f, ...)
lift_lv(..f, ...)  

**Arguments**

.\_f  
A function to lift.

...  
Default arguments for .\_f. These will be evaluated only once, when the lifting factory is called.

.unnamed  
If TRUE, ld or lv will not name the parameters in the lifted function signature. This prevents matching of arguments by name and match by position instead.

.type  
A vector mold or a string describing the type of the input vectors. The latter can be any of the types returned by `typeof()`, or "numeric" as a shorthand for either "double" or "integer".

**Details**

The most important of those helpers is probably `lift_dl()` because it allows you to transform a regular function to one that takes a list. This is often essential for composition with purrr functional tools. Since this is such a common function, `lift()` is provided as an alias for that operation.

**Value**

A function.

**from ... to list(...) or c(...)**

Here dots should be taken here in a figurative way. The lifted functions does not need to take dots per se. The function is simply wrapped a function in `do.call()`, so instead of taking multiple arguments, it takes a single named list or vector which will be interpreted as its arguments. This is particularly useful when you want to pass a row of a data frame or a list to a function and don’t want to manually pull it apart in your function.

**from c(...) to list(...) or ...**

These factories allow a function taking a vector to take a list or dots instead. The lifted function internally transforms its inputs back to an atomic vector. purrr does not obey the usual R casting rules (e.g., `c(1, "2")` produces a character vector) and will produce an error if the types are not compatible. Additionally, you can enforce a particular vector type by supplying .\_type.

**from list(...) to c(...) or ...**

`lift_ld()` turns a function that takes a list into a function that takes dots. `lift_vd()` does the same with a function that takes an atomic vector. These factory functions are the inverse operations of `lift_dl()` and `lift_dv()`.

`lift_vd()` internally coerces the inputs of .\_f to an atomic vector. The details of this coercion can be controlled with .\_type.
See Also

`invoke()`

Examples

```r
### Lifting from ... to list(...) or c(...)

x <- list(x = c(1:100, NA, 1000), na.rm = TRUE, trim = 0.9)
lift_dl(mean)(x)

# Or in a pipe:
mean %>% lift_dl() %>% invoke(x)

# You can also use the lift() alias for this common operation:
lift(mean)(x)

# Default arguments can also be specified directly in lift_dl()
list(c(1:100, NA, 1000)) %>% lift_dl(mean, na.rm = TRUE)()

# lift_dl() and lift_ld() are inverse of each other.
# Here we transform sum() so that it takes a list
fun <- sum %>% lift_dl()
fun(list(3, NA, 4, na.rm = TRUE))

# Now we transform it back to a variadic function
fun2 <- fun %>% lift_ld()
fun2(3, NA, 4, na.rm = TRUE)

# It can sometimes be useful to make sure the lifted function's
# signature has no named parameters, as would be the case for a
# function taking only dots. The lifted function will take a list
# or vector but will not match its arguments to the names of the
# input. For instance, if you give a data frame as input to your
# lifted function, the names of the columns are probably not
# related to the function signature and should be discarded.
lifted_identical <- lift_dl(identical, .unnamed = TRUE)
mtcars[c(1, 1)] %>% lifted_identical()
mtcars[c(1, 2)] %>% lifted_identical()

### Lifting from c(...) to list(...) or ...

# In other situations we need the vector-valued function to take a
# variable number of arguments as with pmap(). This is a job for
# lift_vd():

pmap(mtcars, lift_vd(mean))

# lift_vd() will collect the arguments and concatenate them to a
# vector before passing them to ..f. You can add a check to assert
# the type of vector you expect:
lift_vd(tolower, .type = character(1))("this", "is", "ok")

### Lifting from list(...) to c(...) or ...
```
# cross() normally takes a list of elements and returns their
cartesian product. By lifting it you can supply the arguments as
# if it was a function taking dots:
cross_dots <- lift_ld(cross)
out1 <- cross(list(a = 1:2, b = c("a", "b", "c")))
out2 <- cross_dots(a = 1:2, b = c("a", "b", "c"))
identical(out1, out2)

# This kind of lifting is sometimes needed for function
# composition. An example would be to use pmap() with a function
# that takes a list. In the following, we use some() on each row of
# a data frame to check they each contain at least one element
# satisfying a condition:
mtcars %>% pmap(lift ld(some, partial(`<`, 200)))

# Default arguments for ..f can be specified in the call to
# lift ld()
lift ld(cross, .filter = `==`)(1:3, 1:3) %>% str()

# Here is another function taking a list and that we can update to
# take a vector:

## Not run:
letters %>% glue()  # fails because glue() expects a list
## End(Not run)

letters %>% lift lv(glue())  # succeeds

---

### list_modify

Modify a list

**Description**

`list_modify()` and `list_merge()` recursively combine two lists, matching elements either by name or position. If a sub-element is present in both lists `list_modify()` takes the value from y, and `list_merge()` concatenates the values together.

`update_list()` handles formulas and quosures that can refer to values existing within the input list. Note that this function might be deprecated in the future in favour of a dplyr::mutate() method for lists.

**Usage**

`list_modify(.x, ...)`

`list_merge(.x, ...)`
Arguments

.x List to modify.

New values of a list. Use zap() to remove values.

These values should be either all named or all unnamed. When inputs are all named, they are matched to .x by name. When they are all unnamed, they are matched positionally.

These dots support tidy dots features. In particular, if your functions are stored in a list, you can splice that in with !!!.

Examples

x <- list(x = 1:10, y = 4, z = list(a = 1, b = 2))
str(x)

# Update values
str(list_modify(x, a = 1))
# Replace values
str(list_modify(x, z = 5))
str(list_modify(x, z = list(a = 1:5)))

# Remove values
str(list_modify(x, z = zap()))

# Combine values
str(list_merge(x, x = 11, z = list(a = 2:5, c = 3)))

# All these functions support tidy dots features. Use !!! to splice
# a list of arguments:
l <- list(new = 1, y = zap(), z = 5)
str(list_modify(x, !!!l))

lmap

Apply a function to list-elements of a list

Description

lmap(), lmap_at() and lmap_if() are similar to map(), map_at() and map_if(), with the difference that they operate exclusively on functions that take and return a list (or data frame). Thus, instead of mapping the elements of a list (as in .x[[i]]), they apply a function .f to each subset of size 1 of that list (as in .x[i]). We call those elements list-elements.

Usage

lmap(.x, .f, ...)
lmap_if(.x, .p, .f, ..., .else = NULL)
lmap_at(.x, .at, .f, ...)

Arguments
.
.x
A list or data frame.
.f
A function that takes and returns a list or data frame.
...
Additional arguments passed on to the mapped function.
.p
A single predicate function, a formula describing such a predicate function, or a logical vector of the same length as .x. Alternatively, if the elements of .x are themselves lists of objects, a string indicating the name of a logical element in the inner lists. Only those elements where .p evaluates to TRUE will be modified.
.else
A function applied to elements of .x for which .p returns FALSE.
.at
A character vector of names, positive numeric vector of positions to include, or a negative numeric vector of positions to exclude. Only those elements corresponding to .at will be modified. If the tidyselect package is installed, you can use vars() and the tidyselect helpers to select elements.

Details
Mapping the list-elements .x[i] has several advantages. It makes it possible to work with functions that exclusively take a list or data frame. It enables .f to access the attributes of the encapsulating list, like the name of the components it receives. It also enables .f to return a larger list than the list-element of size 1 it got as input. Conversely, .f can also return empty lists. In these cases, the output list is reshaped with a different size than the input list .x.

Value
If .x is a list, a list. If .x is a data frame, a data frame.

See Also
Other map variants: imap, invoke, map2, map, modify

Examples
# Let's write a function that returns a larger list or an empty list
# depending on some condition. This function also uses the names
# metadata available in the attributes of the list-element
maybe_rep <- function(x) {
  n <- rpois(1, 2)
  out <- rep_len(x, n)
  if (length(out) > 0) {
    names(out) <- paste0(names(x), seq_len(n))
  }
  out
}

# The output size varies each time we map f()
x <- list(a = 1:4, b = letters[5:7], c = 8:9, d = letters[10])
x %>% lmap(maybe_rep)

# We can apply f() on a selected subset of x
x %>% lmap_at(c("a", "d"), maybe_rep)

# Or only where a condition is satisfied
x %>% lmap_if(is.character, maybe_rep)
# A more realistic example would be a function that takes discrete variables in a dataset and turns them into disjunctive tables, a form that is amenable to fitting some types of models.

# A disjunctive table contains only 0 and 1 but has as many columns as unique values in the original variable. Ideally, we want to combine the names of each level with the name of the discrete variable in order to identify them. Given these requirements, it makes sense to have a function that takes a data frame of size 1 and returns a data frame of variable size.

disjoin <- function(x, sep = "_") {
  name <- names(x)
  x <- as.factor(x[[1]])

  out <- lapply(levels(x), function(level) {
    as.numeric(x == level)
  })

  names(out) <- paste(name, levels(x), sep = sep)
  out
}

# Now, we are ready to map disjoin() on each categorical variable of a data frame:
iris %>% lmap_if(is.factor, disjoin)
mtcars %>% lmap_at(c("cyl", "vs", "am"), disjoin)

---

### Description

The map functions transform their input by applying a function to each element and returning a vector the same length as the input.

- `map()`, `map_if()` and `map_at()` always return a list. See the `modify()` family for versions that return an object of the same type as the input.
  - The `_if` and `_at` variants take a predicate function `.p` that determines which elements of `.x` are transformed with `.f`.
- `map_lgl()`, `map_int()`, `map_dbl()` and `map_chr()` each return an atomic vector of the indicated type (or die trying).
  - The return value of `.f` must be of length one for each element of `.x`. If `.f` uses an extractor function shortcut, `.default` can be specified to handle values that are absent or empty. See `as_mapper()` for more on `.default`.
- `map_dfr()` and `map_df()` return data frames created by row-binding and column-binding respectively. They require `dplyr` to be installed.
- `walk()` calls `.f` for its side-effect and returns the input `.x`. 
Usage

map(.x, .f, ...)

map_if(.x, .p, .f, ..., .else = NULL)

map_at(.x, .at, .f, ...)

map_lgl(.x, .f, ...)

map_chr(.x, .f, ...)

map_int(.x, .f, ...)

map_dbl(.x, .f, ...)

map_raw(.x, .f, ...)

map_dfr(.x, .f, ..., .id = NULL)

map_dfc(.x, .f, ...)

walk(.x, .f, ...)

map_depth(.x, .depth, .f, ..., .ragged = FALSE)

Arguments

.x A list or atomic vector.

.f A function, formula, or vector (not necessarily atomic).

If a function, it is used as is.

If a formula, e.g. ~ .x + 2, it is converted to a function. There are three ways to refer to the arguments:

• For a single argument function, use .
• For a two argument function, use .x and .y
• For more arguments, use .1, .2, .3 etc

This syntax allows you to create very compact anonymous functions.

If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of .default will be returned.

... Additional arguments passed on to the mapped function.

.p A single predicate function, a formula describing such a predicate function, or a logical vector of the same length as .x. Alternatively, if the elements of .x are themselves lists of objects, a string indicating the name of a logical element in the inner lists. Only those elements where .p evaluates to TRUE will be modified.

.else A function applied to elements of .x for which .p returns FALSE.

.at A character vector of names, positive numeric vector of positions to include, or a negative numeric vector of positions to exclude. Only those elements corresponding to .at will be modified. If the tidyselect package is installed, you can use vars() and the tidyselect helpers to select elements.
.id  Either a string or NULL. If a string, the output will contain a variable with that name, storing either the name (if .x is named) or the index (if .x is unnamed) of the input. If NULL, the default, no variable will be created. Only applies to _dfr variant.

.depth  Level of .x to map on. Use a negative value to count up from the lowest level of the list.

  • map_depth(x, 0, fun) is equivalent to fun(x).
  • map_depth(x, 1, fun) is equivalent to x <- map(x, fun)
  • map_depth(x, 2, fun) is equivalent to x <- map(x, ~ map(., fun))

.ragged  If TRUE, will apply to leaves, even if they’re not at depth .depth. If FALSE, will throw an error if there are no elements at depth .depth.

Value

All functions return a vector the same length as .x.

map() returns a list, map_lgl() a logical vector, map_int() an integer vector, map_dbl() a double vector, and map_chr() a character vector. map_df(), map_dfc(), map_dfr() all return a data frame. The output of .f will be automatically typed upwards, e.g. logical -> integer -> double -> character.

If .x has names(), the return value preserves those names.

walk() returns the input .x (invisibly). This makes it easy to use in pipe.

Other map variants: imap, invoke, lmap, map2, modify

Examples

```r
1:10 %>%
  map(rnorm, n = 10) %>%
  map_dbl(mean)
```

# Or use an anonymous function
```r
1:10 %>%
  map(function(x) rnorm(10, x))
```

# Or a formula
```r
1:10 %>%
  map(~ rnorm(10, .x))
```

# The names of the input are preserved in the output:
```r
list(foo = 1, bar = 2) %>% map("\+", 10)
```

# Using set_names() with character vectors is handy to keep track of the original inputs:
```r
c("foo", "bar") %>% map_chr(paste0, ":suffix")
```

# Extract by name or position
# .default specifies value for elements that are missing or NULL
```r
l1 <- list(list(a = 1L), list(a = NULL, b = 2L), list(b = 3L))
l1 %>% map("a", .default = "???")
l1 %>% map_int("b", .default = NA)
l1 %>% map_int(2, .default = NA)
```
# Supply multiple values to index deeply into a list
l2 <- list(
  list(num = 1:3, letters[1:3]),
  list(num = 101:103, letters[4:6]),
  list()
)
l2 %>% map(c(2, 2))

# Use a list to build an extractor that mixes numeric indices and names,
# and .default to provide a default value if the element does not exist
l2 %>% map(list("num", 3))
l2 %>% map_int(list("num", 3), .default = NA)

# Use a predicate function to decide whether to map a function:
map_if(iris, is.factor, as.character)

# Specify an alternative with the `.else` argument:
map_if(iris, is.factor, as.character, .else = as.integer)

# A more realistic example: split a data frame into pieces, fit a
# model to each piece, summarise and extract R^2
mtcars %>%
  split(.x, .cyl) %>%
  map(~ lm(mpg ~ wt, data = .x)) %>%
  map(summary) %>%
  map_dbl("r.squared")

# Use map_lgl(), map_dbl(), etc to reduce to a vector.
# * list
mtcars %>% map(sum)
# * vector
mtcars %>% map_dbl(sum)

# If each element of the output is a data frame, use
# map_dfr to row-bind them together:
mtcars %>%
  split(.x, .cyl) %>%
  map_dfr(~ lm(mpg ~ wt, data = .x)) %>%
  map_dfr(~ as.data.frame(t(as.matrix(coef(.)))))
# (if you also want to preserve the variable names see
# the broom package)

# Use `map_depth()` to recursively traverse nested vectors and map
# a function at a certain depth:
x <- list(a = list(foo = 1:2, bar = 3:4), b = list(baz = 5:6))
str(x)
map_depth(x, 2, paste, collapse = "/")

# Equivalent to:
mapping(x, map, paste, collapse = "/")
Description

These functions are variants of `map()` that iterate over multiple arguments simultaneously. They are parallel in the sense that each input is processed in parallel with the others, not in the sense of multicore computing. They share the same notion of "parallel" as `base::pmax()` and `base::pmin()`. `map2()` and `walk2()` are specialised for the two argument case; `pmap()` and `pwalk()` allow you to provide any number of arguments in a list. Note that a data frame is a very important special case, in which case `pmap()` and `pwalk()` apply the function `.f` to each row. `map_dfr()`, `pmap_dfr()` and `map2_dfc()`, `pmap_dfc()` return data frames created by row-binding and column-binding respectively. They require dplyr to be installed.

Usage

```r
map2(.x, .y, .f, ...)  
map2_lgl(.x, .y, .f, ...)  
map2_int(.x, .y, .f, ...)  
map2_dbl(.x, .y, .f, ...)  
map2_chr(.x, .y, .f, ...)  
map2_raw(.x, .y, .f, ...)  
map2_dfr(.x, .y, .f, ..., .id = NULL)  
map2_dfc(.x, .y, .f, ...)  
walk2(.x, .y, .f, ...)  
pmap(.l, .f, ...)  
pmap_lgl(.l, .f, ...)  
pmap_int(.l, .f, ...)  
pmap_dbl(.l, .f, ...)  
pmap_chr(.l, .f, ...)  
pmap_raw(.l, .f, ...)  
pmap_dfr(.l, .f, ..., .id = NULL)  
pmap_dfc(.l, .f, ...)  
pwalk(.l, .f, ...)  
```

Arguments

- `.x, .y` Vectors of the same length. A vector of length 1 will be recycled.
- `.f` A function, formula, or vector (not necessarily atomic).
If a function, it is used as is.
If a formula, e.g. \( \cdot x + 2 \), it is converted to a function. There are three ways to refer to the arguments:

- For a single argument function, use \( . \).
- For a two argument function, use \( .x \) and \( .y \).
- For more arguments, use \( ..1, ..2, ..3 \) etc.

This syntax allows you to create very compact anonymous functions.

If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of \( .\text{default} \) will be returned.

... Additional arguments passed on to the mapped function.
.id Either a string or \( \text{NULL}. \) If a string, the output will contain a variable with that name, storing either the name (if \( .x \) is named) or the index (if \( .x \) is unnamed) of the input. If \( \text{NULL} \), the default, no variable will be created.
Only applies to \( _\text{dfr} \) variant.
.l A list of vectors, such as a data frame. The length of \( .l \) determines the number of arguments that \( .f \) will be called with. List names will be used if present.

Details

Note that arguments to be vectorised over come before \( .f \), and arguments that are supplied to every call come after \( .f \).

Value

An atomic vector, list, or data frame, depending on the suffix. Atomic vectors and lists will be named if \( .x \) or the first element of \( .l \) is named.

If all input is length 0, the output will be length 0. If any input is length 1, it will be recycled to the length of the longest.

Other map variants: \( \text{imap, invoke, lmap, map, modify} \)

Examples

```r
x <- list(1, 10, 100)
y <- list(1, 2, 3)
z <- list(5, 50, 500)

map2(x, y, \( \cdot x + \cdot y \))
# Or just
map2(x, y, `+``)

pmap(list(x, y, z), sum)
# Matching arguments by position
pmap(list(x, y, z), function(a, b, c) a / (b + c))
# Matching arguments by name
l <- list(a = x, b = y, c = z)
```
pmap(l, function(c, b, a) a / (b + c))

# Split into pieces, fit model to each piece, then predict
by_cyl <- mtcars %>% split(.$cyl)
mods <- by_cyl %>% map(~ lm(mpg ~ wt, data = .))
map2(mods, by_cyl, predict)

# Vectorizing a function over multiple arguments
df <- data.frame(x = c("apple", "banana", "cherry"),
                 pattern = c("p", "n", "h"),
                 replacement = c("x", "f", "q"),
                 stringsAsFactors = FALSE)
pmap(df, gsub)
pmap_chr(df, gsub)

# Use `\...\` to absorb unused components of input list .l
df <- data.frame(x = 1:3 + 0.1,
y = 3:1 - 0.1,
z = letters[1:3])
plus <- function(x, y) x + y
## Not run:
# this won't work
pmap(df, plus)
## End(Not run)
# but this will
plus2 <- function(x, y, ...) x + y
pmap_dbl(df, plus2)

# The "p" for "parallel" in pmap() is the same as in base::pmin()
# and base::pmax()
df <- data.frame(x = c(1, 2, 5),
y = c(5, 4, 8))
map2_dbl(df$x, df$y, min)
pmap_dbl(df, min)

# If you want to bind the results of your function rowwise, use map2_dfr() or pmap_dfr()
ex_fun <- function(arg1, arg2){
col <- arg1 + arg2
x <- as.data.frame(col)
}
arg1 <- seq(1, 10, by = 3)
arg2 <- seq(2, 11, by = 3)
df <- map2_dfr(arg1, arg2, ex_fun)
# If instead you want to bind by columns, use map2_dfc() or pmap_dfc()
df2 <- map2_dfc(arg1, arg2, ex_fun)
modify

Modify elements selectively

Description

Unlike `map()` and its variants which always return a fixed object type (list for `map()`, integer vector for `map_int()`, etc), the `modify()` family always returns the same type as the input object.

- `modify()` is a shortcut for `x[[i]] <- f(x[[i]]); return(x)`.
- `modify_if()` only modifies the elements of `x` that satisfy a predicate and leaves the others unchanged. `modify_at()` only modifies elements given by names or positions.
- `modify2()` modifies the elements of `.x` but also passes the elements of `.y` to `.f`, just like `map2()`. `imodify()` passes the names or the indices to `.f` like `imap()` does.
- `modify_depth()` only modifies elements at a given level of a nested data structure.

Usage

modify(.x, .f, ...)

## Default S3 method:
m-modify(.x, .f, ...)

modify_if(.x, .p, .f, ..., .else = NULL)

## Default S3 method:
m-modify_if(.x, .p, .f, ..., .else = NULL)

modify_at(.x, .at, .f, ...)

## Default S3 method:
m-modify_at(.x, .at, .f, ...)

modify2(.x, .y, .f, ...)

imodify(.x, .f, ...)

modify_depth(.x, .depth, .f, ..., .ragged = .depth < 0)

## Default S3 method:
m-modify_depth(.x, .depth, .f, ..., .ragged = .depth < 0)

Arguments

- `.x` A list or atomic vector.
- `.f` A function, formula, or vector (not necessarily atomic).
  If a function, it is used as is.
  If a formula, e.g. `~ x + 2`, it is converted to a function. There are three ways to refer to the arguments:
  - For a single argument function, use .
modify

- For a two argument function, use `.x` and `.y`
- For more arguments, use `..1`, `..2`, `..3` etc

This syntax allows you to create very compact anonymous functions.

If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of `.default` will be returned.

... Additional arguments passed on to the mapped function.

`.p` A single predicate function, a formula describing such a predicate function, or a logical vector of the same length as `.x`. Alternatively, if the elements of `.x` are themselves lists of objects, a string indicating the name of a logical element in the inner lists. Only those elements where `.p` evaluates to TRUE will be modified.

`.else` A function applied to elements of `.x` for which `.p` returns FALSE.

`.at` A character vector of names, positive numeric vector of positions to include, or a negative numeric vector of positions to exclude. Only those elements corresponding to `.at` will be modified. If the tidyselect package is installed, you can use `vars()` and the tidyselect helpers to select elements.

`.y` Vectors of the same length. A vector of length 1 will be recycled.

`.depth` Level of `.x` to map on. Use a negative value to count up from the lowest level of the list.

  - modify_depth(x, 0, fun) is equivalent to `x[] <- fun(x)`.
  - modify_depth(x, 1, fun) is equivalent to `x <- modify(x, fun)
  - modify_depth(x, 2, fun) is equivalent to `x <- modify(x, ~ modify(., fun))

`.ragged` If TRUE, will apply to leaves, even if they’re not at depth `.depth`. If FALSE, will throw an error if there are no elements at depth `.depth`.

Details

Since the transformation can alter the structure of the input; it’s your responsibility to ensure that the transformation produces a valid output. For example, if you’re modifying a data frame, `.f` must preserve the length of the input.

Value

An object the same class as `.x`

Genericity

`modify()` and variants are generic over classes that implement `length()`, `[[` and `[[<-` methods. If the default implementation is not compatible for your class, you can override them with your own methods.

If you implement your own `modify()` method, make sure it satisfies the following invariants:

\[
\text{modify}(x, \text{identity}) \equiv x
\]
\[
\text{modify}(x, \text{compose}(f, g)) \equiv \text{modify}(x, g) \%\% \text{modify}(f)
\]

These invariants are known as the functor laws in computer science.

See Also

Other map variants: `imap`, `invoke`, `lmap`, `map2`, `map`
### Examples

# Convert factors to characters
iris %>%
  modify_if(is.factor, as.character) %>%
  str()

# Specify which columns to map with a numeric vector of positions:
mtcars %>%
  modify_at(c(1, 4, 5), as.character) %>%
  str()

# Or with a vector of names:
mtcars %>%
  modify_at(c("cyl", "am"), as.character) %>%
  str()

list(x = rbernoulli(100), y = 1:100) %>%
  transpose() %>%
  modify_if("x", ~ update_list(., y = ~ y * 100)) %>%
  transpose() %>%
  simplify_all()

# Use modify2() to map over two vectors and preserve the type of
# the first one:
x <- c(foo = 1L, bar = 2L)
y <- c(TRUE, FALSE)
modify2(x, y, ~ if (.y) .x else 0L)

# Use a predicate function to decide whether to map a function:
modify_if(iris, is.factor, as.character)

# Specify an alternative with the `.else` argument:
modify_if(iris, is.factor, as.character, .else = as.integer)

# Modify at specified depth ---------------------------
l1 <- list(
  obj1 = list(
    prop1 = list(param1 = 1:2, param2 = 3:4),
    prop2 = list(param1 = 5:6, param2 = 7:8)
  ),
  obj2 = list(
    prop1 = list(param1 = 9:10, param2 = 11:12),
    prop2 = list(param1 = 12:14, param2 = 15:17)
  )
)

# In the above list, "obj" is level 1, "prop" is level 2 and "param"
# is level 3. To apply sum() on all params, we map it at depth 3:
l1 %>%
  modify_depth(3, sum) %>%
  str()

# Note that vectorised operations will yield the same result when
# applied at the list level as when applied at the atomic result.
# The former is more efficient because it takes advantage of
# vectorisation.
l1 %>%
  modify_depth(3, `+`, 100L)
l1 %>%
  modify_depth(4, `+`, 100L)

# modify() lets us pluck the elements prop1/param2 in obj1 and obj2:
l1 %>%
  modify(c("prop1", "param2")) %>%
  str()
# But what if we want to pluck all param2 elements? Then we need to
# act at a lower level:
l1 %>% modify_depth(2, "param2") %>% str()

# modify_depth() can be with other purrr functions to make them operate at
# a lower level. Here we ask pmap() to map paste() simultaneously over all
# elements of the objects at the second level. paste() is effectively
# mapped at level 3.
l1 %>% modify_depth(2, ~ pmap(., paste, sep = " / ")) %>% str()

---

**modify_in**

**Description**

- `modify_in()` applies a function to a pluck location, assigns the result back to that location
  with `assign_in()`, and returns the modified data structure.
  
  The pluck location must exist.

**Usage**

```r
modify_in(.x, .where, .f, 

assign_in(x, where, value)
```

**Arguments**

- `.x` A vector or environment
- `.where`, `where` A pluck location, as a numeric vector of positions, a character vector of names, or a list combining both. The location must exist in the data structure.
- `.f` A function to apply at the pluck location given by `.where`.
- `...` Arguments passed to `.f`.
- `x` A vector or environment
- `value` A value to replace in `.x` at the pluck location.

**See Also**

`pluck()`

**Examples**

```r
# Recall that pluck() returns a component of a data structure that
# might be arbitrarily deep
x <- list(list(bar = 1, foo = 2))
pluck(x, 1, "foo")

# Use assign_in() to modify the pluck location:
assign_in(x, list(1, "foo"), 100)
```
# modify_in() applies a function to that location and update the
# element in place:
modify_in(x, list(1, "foo"), ~ .x * 200)

# Additional arguments are passed to the function in the ordinary way:
modify_in(x, list(1, "foo"), `+`, 100)

---

### negate

Negate a predicate function.

#### Usage

```r
negate(.p, .default = FALSE)
```

#### Arguments

- `.p`  
  A single predicate function, a formula describing such a predicate function, or a logical vector of the same length as `.x`. Alternatively, if the elements of `.x` are themselves lists of objects, a string indicating the name of a logical element in the inner lists. Only those elements where `.p` evaluates to `TRUE` will be modified.

- `.default`  
  Optional additional argument for extractor functions (i.e. when `.f` is character, integer, or list). Returned when value is absent (does not exist) or empty (has length 0). `.null` is deprecated; please use `.default` instead.

#### Value

A new predicate function.

#### Examples

```r
negate("x")
negate(is.null)
negate(~ .x > 0)
```

```r
x <- transpose(list(x = 1:10, y = rbernoulli(10)))
x %>% keep("y") %>% length()
x %>% keep(negate("y")) %>% length()
# Same as
x %>% discard("y") %>% length()
```

---

### null-default

Default value for NULL

#### Description

These objects are imported from other packages. Follow the links below to see their documentation.

- `rlang`
Partial apply a function, filling in some arguments.

Description

Partial function application allows you to modify a function by pre-filling some of the arguments. It is particularly useful in conjunction with functionals and other function operators. Note that an argument can only be partialised once.

Usage

`partial(.f, ..., .env = NULL, .lazy = NULL, .first = NULL)`

Arguments

- `.f`: a function. For the output source to read well, this should be a named function.
- `...`: named arguments to `.f` that should be partially applied. Pass an empty `... = ` argument to specify the position of future arguments relative to partialised ones. See `rlang::call_modify()` to learn more about this syntax. These dots support quasiquotation and quosures. If you unquote a value, it is evaluated only once at function creation time. Otherwise, it is evaluated each time the function is called.
- `.env`: Soft-deprecated as of purrr 0.3.0. The environments are now captured via quosures.
- `.lazy`: Soft-deprecated as of purrr 0.3.0. Please unquote the arguments that should be evaluated once at function creation time.
- `.first`: Soft-deprecated as of purrr 0.3.0. Please pass an empty argument `... = ` to specify the position of future arguments.

Examples

```r
# Partial is designed to replace the use of anonymous functions for # filling in function arguments. Instead of:
compact1 <- function(x) discard(x, is.null)

# we can write:
compact2 <- partial(discard, .p = is.null)

# partial() works fine with functions that do non-standard # evaluation
my_long_variable <- 1:10
plot2 <- partial(plot, my_long_variable)
plot2()
plot2(runif(10), type = "l")

# Note that you currently can't partialise arguments multiple times:
my_mean <- partial(mean, na.rm = TRUE)
my_mean <- partial(my_mean, na.rm = FALSE)
try(my_mean(1:10))
```
# The evaluation of arguments normally occurs "lazily". Concretely, # this means that arguments are repeatedly evaluated across invocations:
f <- partial(runif, n = rpois(1, 5))
f
f()
f()

# You can unquote an argument to fix it to a particular value. # Unquoted arguments are evaluated only once when the function is created:
f <- partial(runif, n = !!rpois(1, 5))
f
f()
f()

# By default, partialised arguments are passed before new ones:
my_list <- partial(list, 1, 2)
my_list("foo")

# Control the position of these arguments by passing an empty # `... =` argument:
my_list <- partial(list, 1, ... = , 2)
my_list("foo")

---

**pluck**

Pluck or chuck a single element from a vector or environment

**Description**

pluck() and chuck() implement a generalised form of `[ ]` that allow you to index deeply and flexibly into data structures. pluck() consistently returns NULL when an element does not exist, chuck() always throws an error in that case.

**Usage**

pluck(.x, ..., .default = NULL)

chuck(.x, ...)

pluck(.x, ...) <- value

**Arguments**

.x, x  A vector or environment

...  A list of accessors for indexing into the object. Can be an integer position, a string name, or an accessor function (except for the assignment variants which only support names and positions). If the object being indexed is an S4 object, accessing it by name will return the corresponding slot. These dots support tidy dots features. In particular, if your accessors are stored in a list, you can splice that in with `!!!`.

.default  Value to use if target is empty or absent.

.value  A value to replace in .x at the pluck location.
Details

- You can pluck or chuck with standard accessors like integer positions and string names, and also accepts arbitrary accessor functions, i.e. functions that take an object and return some internal piece.
  This is often more readable than a mix of operators and accessors because it reads linearly and is free of syntactic cruft. Compare: accessor(x[[1]])$foo to pluck(x, 1, accessor, "foo").
- These accessors never partial-match. This is unlike $ which will select the disp object if you write mtcars$di.

See Also

attr_getter() for creating attribute getters suitable for use with pluck() and chuck(). modify_in() for applying a function to a pluck location.

Examples

# Let's create a list of data structures:
obj1 <- list("a", list(1, elt = "foo"))
obj2 <- list("b", list(2, elt = "bar"))
x <- list(obj1, obj2)

# pluck() provides a way of retrieving objects from such data structures using a combination of numeric positions, vector or list names, and accessor functions.
# Numeric positions index into the list by position, just like `[[`:
pluck(x, 1)
x[[1]]
pluck(x, 1, 2)
x[[1]][[2]]

# Supply names to index into named vectors:
pluck(x, 1, 2, "elt")
x[[1]][[2]][["elt"]]

# By default, pluck() consistently returns `NULL` when an element does not exist:
pluck(x, 10, .default = NA)
try(x[[10]])

# You can also supply a default value for non-existing elements:
pluck(x, 10, .default = NA)

# If you prefer to consistently fail for non-existing elements, use the opinionated variant chuck():
chuck(x, 1)
try(chuck(x, 10))
try(chuck(x, 1, 10))

# The map() functions use pluck() by default to retrieve multiple values from a list:
map(x, 2)

# Pass multiple indexes with a list:
map(x, list(2, "elt"))

# This is equivalent to:
map(x, pluck, 2, "elt")

# You can also supply a default:
map(x, list(2, "elt", 10), .default = "superb default")

# Or use the strict variant:
try(map(x, chuck, 2, "elt", 10))

# You can also assign a value in a pluck location with pluck<-
pluck(x, 2, 2, "elt") <- "quuux"

x

# This is a shortcut for the prefix function assign_in():
y <- assign_in(x, list(2, 2, "elt"), value = "QUUUX")
y

# pluck() also supports accessor functions:
my_element <- function(x) x[[2]]$elt

# The accessor can then be passed to pluck:
pluck(x, 1, my_element)
pluck(x, 2, my_element)

# Even for this simple data structure, this is more readable than
# the alternative form because it requires you to read both from
# right-to-left and from left-to-right in different parts of the
# expression:
my_element(x[[1]])

# If you have a list of accessors, you can splice those in with `!!`:    idx <- list(1, my_element)
pluck(x, !!!idx)

---

**prepend**

**Prepend a vector**

### Description

This is a companion to `append()` to help merging two lists or atomic vectors. `prepend()` is a clearer semantic signal than `c()` that a vector is to be merged at the beginning of another, especially in a pipe chain.

### Usage

`prepend(x, values, before = 1)`
Arguments

x the vector to be modified.
values to be included in the modified vector.
before a subscript, before which the values are to be appended.

Value

A merged vector.

Examples

x <- as.list(1:3)
x %>% append("a")
x %>% prepend("a")
x %>% prepend(list("a", "b"), before = 3)

Description

These helpers create rate settings that you can pass to insistently(). You can also use them in your own functions with rate_sleep().

Usage

rate_delay(pause = 1, max_times = Inf)
rate_backoff(pause_base = 1, pause_cap = 60, pause_min = 1,
max_times = 3, jitter = TRUE)
is_rate(x)

Arguments

pause Delay between attempts in seconds.
max_times Maximum number of requests to attempt.
pause_base, pause_cap
rate_backoff() uses an exponential back-off so that each request waits pause_base * 2^i seconds, up to a maximum of pause_cap seconds.
pause_min Minimum time to wait in the backoff; generally only necessary if you need pauses less than one second (which may not be kind to the server, use with caution!).
jitter Whether to introduce a random jitter in the waiting time.
x An object to test.

See Also

rate_sleep(), insistently()
Examples

# A delay rate waits the same amount of time:
rate <- rate_delay(0.02)
for (i in 1:3) rate_sleep(rate, quiet = FALSE)

# A backoff rate waits exponentially longer each time, with random
# jitter by default:
rate <- rate_backoff(pause_base = 0.2, pause_min = 0.005)
for (i in 1:3) rate_sleep(rate, quiet = FALSE)

rate_sleep
Wait for a given time

Description

If the rate’s internal counter exceeds the maximum number of times it is allowed to sleep, rate_sleep() throws an error of class purrr_error_rate_excess.

Usage

rate_sleep(rate, quiet = TRUE)
rate_reset(rate)

Arguments

rate A rate object determining the waiting time.
quiet If FALSE, prints a message displaying how long until the next request.

Details

Call rate_reset() to reset the internal rate counter to 0.

See Also

rate_backoff(), insistently()

rbernoulli
Generate random sample from a Bernoulli distribution

Description

Generate random sample from a Bernoulli distribution

Usage

rbernoulli(n, p = 0.5)
**reduce**

**Arguments**

- `n` Number of samples
- `p` Probability of getting TRUE

**Value**

A logical vector

**Examples**

- `rbernoulli(10)`
- `rbernoulli(100, 0.1)`

---

**rdunif**

Generate random sample from a discrete uniform distribution

**Description**

Generate random sample from a discrete uniform distribution

**Usage**

`rdunif(n, b, a = 1)`

**Arguments**

- `n` Number of samples to draw.
- `a, b` Range of the distribution (inclusive).

**Examples**

- `table(rdunif(1e3, 10))`
- `table(rdunif(1e3, 10, -5))`

---

**reduce**

Reduce a list to a single value by iteratively applying a binary function

**Description**

`reduce()` is an operation that combines the elements of a vector into a single value. The combination is driven by `.f`, a binary function that takes two values and returns a single value: reducing `f` over `1:3` computes the value `f(f(1, 2), 3)`.

**Usage**

- `reduce(.x, .f, ..., .init, .dir = c("forward", "backward"))`
- `reduce2(.x, .y, .f, ..., .init)`
reduce

Arguments

\texttt{.x} A list or atomic vector.
\texttt{.f} For \texttt{reduce()}, and \texttt{accumulate()}, a 2-argument function. The function will be passed the accumulated value as the first argument and the "next" value as the second argument.

For \texttt{reduce2()} and \texttt{accumulate2()}, a 3-argument function. The function will be passed the accumulated value as the first argument, the next value of \texttt{.x} as the second argument, and the next value of \texttt{.y} as the third argument.

The reduction terminates early if \texttt{.f} returns a value wrapped in a \texttt{done()}. Additional arguments passed on to the mapped function.
\texttt{.init} If supplied, will be used as the first value to start the accumulation, rather than using \texttt{.x[1]}. This is useful if you want to ensure that \texttt{reduce} returns a correct value when \texttt{.x} is empty. If missing, and \texttt{.x} is empty, will throw an error.
\texttt{.dir} The direction of reduction as a string, one of "forward" (the default) or "backward". See the section about direction below.
\texttt{.y} For \texttt{reduce2()} and \texttt{accumulate2()}, an additional argument that is passed to \texttt{.f}. If \texttt{init} is not set, \texttt{.y} should be 1 element shorter than \texttt{.x}.

Direction

When \texttt{.f} is an associative operation like + or \texttt{c()}, the direction of reduction does not matter. For instance, reducing the vector 1:3 with the binary function + computes the sum ((1 + 2) + 3) from the left, and the same sum (1 + (2 + 3)) from the right.

In other cases, the direction has important consequences on the reduced value. For instance, reducing a vector with \texttt{list()} from the left produces a left-leaning nested list (or tree), while reducing \texttt{list()} from the right produces a right-leaning list.

Life cycle

\texttt{reduce_right()} is soft-deprecated as of purrr 0.3.0. Please use the \texttt{.dir} argument of \texttt{reduce()} instead. Note that the algorithm has changed. Whereas \texttt{reduce_right()} computed \texttt{f(f(3, 2), 1)}, \texttt{reduce(.dir = "backward")} computes \texttt{f(1, f(2, 3))}. This is the standard way of reducing from the right.

To update your code with the same reduction as \texttt{reduce_right()}, simply reverse your vector and use a left reduction:

# Before:
reduce_right(1:3, f)

# After:
reduce(rev(1:3), f)

\texttt{reduce2_right()} is soft-deprecated as of purrr 0.3.0 without replacement. It is not clear what algorithmic properties should a right reduction have in this case. Please reach out if you know about a use case for a right reduction with a ternary function.

See Also

\texttt{accumulate()} for a version that returns all intermediate values of the reduction.
Examples

# Reducing `+` computes the sum of a vector while reducing `*` computes the product:

```r
1:3 %>% reduce(`+`)  # 6
1:10 %>% reduce(`*`)  # 360
```

# When the operation is associative, the direction of reduction does not matter:

```r
reduce(1:4, `+`)  # 10
reduce(1:4, `+`, .dir = "backward")  # 10
```

# However with non-associative operations, the reduced value will be different as a function of the direction. For instance, `\texttt{list()}` will create left-leaning lists when reducing from the right, and right-leaning lists otherwise:

```r
str(reduce(1:4, list))  # left-leaning
str(reduce(1:4, list, .dir = "backward"))  # right-leaning
```

# `reduce2()` takes a ternary function and a second vector that is one element smaller than the first vector:

```r
paste2 <- function(x, y, sep = ".") paste(x, y, sep = sep)
letters[1:4] %>% reduce(paste2)
letters[1:4] %>% reduce2(c("-\", ".\", "-\"), paste2)
```

```r
x <- list(c(0, 1), c(2, 3), c(4, 5))
y <- list(c(6, 7), c(8, 9))
reduce2(x, y, paste)
```

# You can shortcircuit a reduction and terminate it early by returning a value wrapped in a `done()` function. In the following example we return early if the result-so-far, which is passed on the LHS, meets a condition:

```r
paste3 <- function(out, input, sep = ".") {
  if (nchar(out) > 4) {
    return(done(out))
  }
  paste(out, input, sep = sep)
}
letters %>% reduce(paste3)
```

# Here the early return branch checks the incoming inputs passed on the RHS:

```r
paste4 <- function(out, input, sep = ".") {
  if (input == "j") {
    return(done(out))
  }
  paste(out, input, sep = sep)
}
letters %>% reduce(paste4)
```

---

**rep_along**

Repeat a value with matching length
rerun

Description
These objects are imported from other packages. Follow the links below to see their documentation.

rlang  rep_along

rerun  Re-run expressions multiple times.

Description

Questioning
This is a convenient way of generating sample data. It works similarly to `replicate(..., simplify = FALSE).

Usage
rerun(.n, ...)

Arguments

.n  Number of times to run expressions
...

Expressions to re-run.

Value
A list of length .n. Each element of ... will be re-run once for each .n.

There is one special case: if there’s a single unnamed input, the second level list will be dropped. In this case, rerun(n, x) behaves like replicate(n, x, simplify = FALSE).

Lifecycle
rerun() is in the questioning lifecycle stage because we are no longer convinced NSE functions are a good fit for purrr. Also, rerun(n, x) can just as easily be expressed as map(1:n, ~ x) (with the added benefit of being passed the current index as argument to the lambda).

Examples
10 %>% rerun(rnorm(5))
10 %>%
  rerun(x = rnorm(5), y = rnorm(5)) %>%
  map_dbl(~ cor(.x$x, .x$y))
safely

Capture side effects.

Description

These functions wrap functions so that instead of generating side effects through printed output, messages, warnings, and errors, they return enhanced output. They are all adverbs because they modify the action of a verb (a function).

Usage

safely(.f, otherwise = NULL, quiet = TRUE)

quietly(.f)

possibly(.f, otherwise, quiet = TRUE)

auto_browse(.f)

Arguments

.f A function, formula, or vector (not necessarily atomic).
If a function, it is used as is.
If a formula, e.g. \( \sim .x + 2 \), it is converted to a function. There are three ways to refer to the arguments:
- For a single argument function, use .
- For a two argument function, use .x and .y
- For more arguments, use ..1, ..2, ..3 etc

This syntax allows you to create very compact anonymous functions.

If character vector, numeric vector, or list, it is converted to an extractor function. Character vectors index by name and numeric vectors index by position; use a list to index by position and name at different levels. If a component is not present, the value of .default will be returned.

otherwise Default value to use when an error occurs.

quiet Hide errors (TRUE, the default), or display them as they occur?

Value

safely: wrapped function instead returns a list with components result and error. If an error occurred, error is an error object and result has a default value (otherwise). Else error is NULL.

quietly: wrapped function instead returns a list with components result, output, messages and warnings.

possibly: wrapped function uses a default value (otherwise) whenever an error occurs.
set_names

Examples

```r
safe_log <- safely(log)
safe_log(10)
safe_log("a")

list("a", 10, 100) %>%
  map(safe_log) %>%
  transpose()

# This is a bit easier to work with if you supply a default value
# of the same type and use the simplify argument to transpose():
safe_log <- safely(log, otherwise = NA_real_)
list("a", 10, 100) %>%
  map(safe_log) %>%
  transpose() %>%
  simplify_all()

# To replace errors with a default value, use possibly().
list("a", 10, 100) %>%
  map_dbl(possibly(log, NA_real_))

# For interactive usage, auto_browse() is useful because it automatically
# starts a browser() in the right place.
f <- function(x) {
y <- 20
if (x > 5) {
  stop("!")
} else {
  x
}
}
if (interactive()) {
  map(1:6, auto_browse(f))
}

# It doesn't make sense to use auto_browse with primitive functions,
# because they are implemented in C so there's no useful environment
# for you to interact with.
```

---

set_names

Set names in a vector

Description

These objects are imported from other packages. Follow the links below to see their documentation.

rlang set_names
splice

Splice objects and lists of objects into a list

Description

Questioning

This splices all arguments into a list. Non-list objects and lists with a S3 class are encapsulated in a list before concatenation.

Usage

splice(...)

Arguments

...  Objects to concatenate.

Value

A list.

Life cycle

splice() is in the questioning lifecycle stage as of purrr 0.3.0. We are now favouring the !!! syntax enabled by rlang::list2().

Examples

inputs <- list(arg1 = "a", arg2 = "b")

# splice() concatenates the elements of inputs with arg3
splice(inputs, arg3 = c("c1", "c2")) %>% str()
list(inputs, arg3 = c("c1", "c2")) %>% str()
c(inputs, arg3 = c("c1", "c2")) %>% str()

transpose

Transpose a list.

Description

Transpose turns a list-of-lists "inside-out": it turns a pair of lists into a list of pairs, or a list of pairs into pair of lists. For example, if you had a list of length n where each component had values a and b, transpose() would make a list with elements a and b that contained lists of length n. It’s called transpose because x[[1]][[2]] is equivalent to transpose(x)[[2]][[1]].

Usage

transpose(.l, .names = NULL)
vec_depth

Arguments

- `.l` A list of vectors to transpose. The first element is used as the template; you’ll get a warning if a subsequent element has a different length.
- `.names` For efficiency, `transpose()` bases the return structure on the first component of `.l` by default. Specify `.names` to override this.

Details

Note that `transpose()` is its own inverse, much like the transpose operation on a matrix. You can get back the original input by transposing it twice.

Value

A list with indexing transposed compared to `.l`.

Examples

```r
x <- rerun(5, x = runif(1), y = runif(5))
x %>% str()
x %>% transpose() %>% str()
# Back to where we started
x %>% transpose() %>% transpose() %>% str()

# transpose() is useful in conjunction with safely() & quietly()
x <- list("a", 1, 2)
y <- x %>% map(safely(log))
y %>% str()
y %>% transpose() %>% str()

# Use simplify_all() to reduce to atomic vectors where possible
x %>% list(a = 1, b = 2), list(a = 3, b = 4), list(a = 5, b = 6))
x %>% transpose()
x %>% transpose() %>% simplify_all()

# Provide explicit component names to prevent loss of those that don’t
# appear in first component
ll <- list(
  list(x = 1, y = "one"),
  list(z = "deux", x = 2)
)
ll %>% transpose()
nms <- ll %>% map(names) %>% reduce(union)
ll %>% transpose(.names = nms)
```

vec_depth

Compute the depth of a vector

Description

The depth of a vector is basically how many levels that you can index into it.

Usage

```r
vec_depth(x)
```
Arguments

x

A vector

Value

An integer.

Examples

x <- list(
    list(),
    list(list()),
    list(list(list(1)))
)
vec_depth(x)
x %>% map_int(vec_depth)

---

zap  Zap an element

Description

These objects are imported from other packages. Follow the links below to see their documentation.

rlang zap
