Package ‘spgrass6’

February 8, 2016

Version 0.8-9
Date 2016-02-08
Title Interface Between GRASS 6+ Geographical Information System and R
Description Interpreted interface between GRASS 6+ geographical information system and R, based on starting R from within the GRASS environment, or running free-standing R in a temporary GRASS location; the package provides facilities for using all GRASS commands from the R command line. This package may not be used for GRASS 7, for which rgrass7 should be used.
Depends R (>= 2.12), sp (>= 0.9), XML
Imports stats, utils, methods
Suggests rgdal (>= 0.8-8)
SystemRequirements GRASS (>= 6.3, < 7)
License GPL (>= 2)
URL http://grass.osgeo.org/
NeedsCompilation no
Author Roger Bivand [cre, aut],

spgrass6-package Interface between GRASS geographical information system and R

Description

Interpreted interface between GRASS geographical information system, versions 6 and 7, and R, based on starting R from within the GRASS environment, or on running R stand-alone and creating a throw-away GRASS environment from within R. The interface uses classes defined in the sp package to hold spatial data.

Details

Index:

- readRAST: read GRASS raster files
- writeRAST: write GRASS raster files
- readVECT: read GRASS vector object files
- writeVECT: write GRASS vector object files
- gmeta: read GRASS metadata from the current LOCATION
- getLocationProj: return a PROJ.4 string of projection information
- gmeta2grd: create a GridTopology object from the GRASS region
- vInfo: return vector geometry information
- vColumns: return vector database columns information
- vDataCount: return count of vector database rows
- vect2neigh: return area neighbours with shared boundary length

Further information may be found in the document doc/spgrass_0.3.pdf in the directory returned by system.file("", package="spgrass6").

Maintainer: Roger Bivand <Roger.Bivand@nhh.no>

Examples

```r
if (nchar(Sys.getenv("GISRC")) > 0) {
  require(rgdal)
  soilsph <- readRAST("soils.ph", ignore.stderr=TRUE, plugin=FALSE)
  summary(soilsph)
  grd <- gmeta2grd(ignore.stderr=TRUE)
  grd
  set.seed(1)
}```
pts <- spsample(soilsh, 200, "random")
sample <- SpatialPointsDataFrame(pts, data=over(pts, soilsh))
summary(sample)
writeVECT(sample, "sp_dem", v.in.ogr_flags="overwrite", ignore.stderr=TRUE)
bugsDF <- readVECT("bugsites", ignore.stderr=TRUE, mapset="PERMANENT")
summary(bugsDF)

vInfo("streams", ignore.stderr=TRUE)
vColumns("streams", ignore.stderr=TRUE)
vDataCount("streams", ignore.stderr=TRUE)
streams <- readVECT("streams", type="line,boundary",
remove.duplicates=FALSE, ignore.stderr=TRUE, plugin=FALSE)
summary(streams)
}

---

execGRASS  

Run GRASS commands

Description

The functions provide an interface to GRASS commands run through system, based on the values returned by the --interface description flag using XML parsing. If required parameters are omitted, and have declared defaults, the defaults will be used.

Usage

execGRASS(cmd, flags = NULL, ..., parameters = NULL, intern = NULL, ignore.stderr = NULL, Sys_ignore.stdout=FALSE, Sys_wait=TRUE, Sys_input=NULL, Sys_show.stdout.on.console=TRUE, Sys_minimized=FALSE, Sys_invisible=TRUE, echoCmd=NULL, redirect=FALSE, legacyExec=NULL)
doGRASS(cmd, flags = NULL, ..., parameters = NULL, echoCmd=NULL, legacyExec=FALSE)
parseGRASS(cmd, legacyExec=FALSE)
## S3 method for class 'GRASS_interface_desc'
print(x, ...)
getXMLencoding()
setXMLencoding(enc)

Arguments

cmd

GRASS command name

flags

character vector of GRASS command flags

... for execGRASS and doGRASS, GRASS module parameters given as R named arguments directly. For the print method, other arguments to print method. The storage modes of values passed must match those required in GRASS, so a single GRASS string must be a character vector of length 1, a single GRASS integer must be an integer vector of length 1 (may be an integer constant such as 10L), and a single GRASS float must be a numeric vector of length 1. For multiple values, use vectors of suitable length
parameters list of GRASS command parameters, used if GRASS parameters are not given as R arguments directly; the two methods for passing GRASS parameters may not be mixed. The storage modes of values passed must match those required in GRASS, so a single GRASS string must be a character vector of length 1, a single GRASS integer must be an integer vector of length 1 (may be an integer constant such as 10L), and a single GRASS float must be a numeric vector of length 1. For multiple values, use vectors of suitable length.

intern default NULL, in which case set internally from get.useInternOption; a logical (not ‘NA’) which indicates whether to make the output of the command an R object. Not available unless ‘popen’ is supported on the platform.

ignore.stderr default NULL, taking the value set by set.ignore.stderrOption, a logical indicating whether error messages written to ‘stderr’ should be ignored.

Sys.ignore.stdout, Sys.wait, Sys.input pass extra arguments to system

Sys.show.output.on.console, Sys.minimized, Sys.invisible pass extra arguments to system on Windows systems only.

echoCmd default NULL, taking the logical value set by set.echoCmdOption, print GRASS command to be executed to console.

redirect default FALSE, if TRUE, add “2>&1” to the command string and set intern to TRUE; only used in legacy mode.

legacyExec default NULL, taking the logical value set by set.legacyExecOption which is initialised to FALSE on “unix” platforms and TRUE otherwise. If TRUE, use system, if FALSE use system2 and divert stderr to temporary file to record error messages and warnings from GRASS modules.

x object to be printed.

enc character string to replace UTF-8 in header of XML data generated by GRASS module –interface-description output when the internationalised messages are not in UTF-8 (known to apply to French, which is in latin1).

Details

parseGRASS checks to see whether the GRASS command has been parsed already and cached in this session; if not, it reads the interface description, parses it and caches it for future use. doGRASS assembles a proposed GRASS command with flags and parameters as a string, wrapping parseGRASS, and execGRASS is a wrapper for doGRASS, running the command through system (from 0.7-4, the ... argument is not used for passing extra arguments for system). The command string is termed proposed, because not all of the particular needs of commands are provided by the interface description, and no check is made for the existence of input objects. Support for multiple parameter values added with help from Patrick Caldon. Support for defaults and for direct use of GRASS parameters instead of a parameter list suggested by Rainer Krug.

Value

parseGRASS returns a GRASS_interface_desc object, doGRASS returns a character string with a proposed GRASS command - the expanded command name is returned as an attribute, and execGRASS returns what system or system2 return, particularly depending on the intern argument when the character strings output by GRASS modules are returned. If intern is FALSE,
execGRASS

system returns the module exit code, while system2 returns the module exit code with “resOut” and “resErr” attributes.

Note

If any package command fails with a UTF-8 error from the XML package, try using setXMLencoding to work around the problem that GRASS modules declare –interface-description output as UTF-8 without ensuring that it is (French is of 6.4.0 RC5 latin1).

Examples

if (nchar(Sys.getenv("GISRC")) > 0) {
  echoCmd <- get.echoCmdOption()
  set.echoCmdOption(TRUE)
  print(parseGRASS("r.slope.aspect"))
  doGRASS("r.slope.aspect", flags=c("overwrite"),
      elevation="elevation.dem", slope="slope", aspect="aspect")
  pars <- list(elevation="elevation.dem", slope="slope", aspect="aspect")
  doGRASS("r.slope.aspect", flags=c("overwrite"), parameters=pars)
  print(parseGRASS("r.buffer"))
  doGRASS("r.buffer", flags=c("overwrite"), input="bugsites", output="bmap",
      distances=seq(1000,15000,1000))
  pars <- list(input="bugsites", output="bmap", distances=seq(1000,15000,1000))
  doGRASS("r.buffer", flags=c("overwrite"), parameters=pars)
  set.echoCmdOption(echoCmd)
  try(res <- execGRASS("r.stats", input = "fire_blocksgg", # no such file
      flags = c("C", "n"), silent=FALSE))
  res <- execGRASS("r.stats", input = "fire_blocksgg", flags = c("C", "n"),
      legacyExec=TRUE)
  print(res)
  if (res != 0) {
    resERR <- execGRASS("r.stats", input = "fire_blocksgg",
        flags = c("C", "n"), redirect=TRUE, legacyExec=TRUE)
    print(resERR)
  }
}
Description

GRASS LOCATION metadata are read into a list in R; helper function getLocationProj returns an spproj-compliant PROJ.4 string of projection information. The helper function gmeta2grd creates a GridTopology object from the current GRASS mapset region definitions. The function gmeta and gmeta6 are identical and gmeta6 is maintained only for backward compatibility and might be deprecated.

Usage

```r
getLocationProj(ignore.stderr = FALSE)
gmeta2grd(ignore.stderr = FALSE)
## S3 method for class 'gmeta'
print(x, ...)  
get.ignore.stderrOption()
get.stop_on_no_flags_parasOption()
get.useGDALOption()
get.pluginOption()
get.echoCmdOption()
get.useInternOption()
get.legacyExecOption()
get.defaultflagsOption()
get.suppressEchoCmdInFuncOption()
set.ignore.stderrOption(value)
set.stop_on_no_flags_parasOption(value)
set.useGDALOption(value)
set.pluginOption(value)
set.echoCmdOption(value)
set.useInternOption(value)
set.legacyExecOption(value)
set.defaultflagsOption(value)
set.suppressEchoCmdInFuncOption(value)
```

Arguments

- `ignore.stderr`: default FALSE, can be set to TRUE to silence system() output to standard error; does not apply on Windows platforms
- `x`: S3 object returned by gmeta
- `...`: arguments passed through print method
- `value`: logical value for setting options on `ignore.stderr` set by default on package load to FALSE, `stop_on_no_flags_paras` set by default on package load to
TRUE, useGDAL set by default on package load to TRUE, plugin set by default on package load to NULL, echoCmd set by default on package load to FALSE. useIntern sets the intern argument globally; legacyExec sets the legacyExec option globally, but is initialized to FALSE on unix systems (all but Windows) and TRUE on Windows; defaultFlags is initialized to NULL, but may be a character vector with values from c("quiet", "verbose") suppressEchoCmdInFunc default TRUE suppresses the effect of echoCmd within package functions, may be set FALSE for debugging.

Value
Returns list of g.gisenv, g.region -g3, and g.proj values

Author(s)
Roger S. Bivand, e-mail: <Roger.Bivand@nhh.no.>

Examples

```r
if (nchar(Sys.getenv("GISRC")) > 0) {
  G <- gmeta()
  print(G)
  CRS(getLocationProj())
  grd <- gmeta2grd()
  print(grd)
  ncells <- prod(slot(grd, "cells.dim"))
  df <- data.frame(k=rep(1, ncells))
  mask_SG <- SpatialGridDataFrame(grd, data=df)
  print(summary(mask_SG))
}
```

initGRASS    Initiate GRASS session

Description
Run GRASS interface in an R session not started within GRASS. In general, most users will use initGRASS in throwaway locations, to use GRASS modules on R objects without the need to define and populate a location. The function initializes environment variables used by GRASS, the .gisrc used by GRASS for further environment variables, and a temporary location.

The locking functions are used internally, but are exposed for experienced R/GRASS scripters needing to use the GRASS module “g.mapset” through initGRASS in an existing GRASS location. In particular, “g.mapset” may leave a .gislock file in the current MAPSET, so it may be important to call unlink_.gislock to clean up before quitting the R session.
Usage

```
initGRASS(gisBase, home, SG, gisDbase, location, mapset, override = FALSE,
          use_g_dirseps.exe = TRUE, pid)
get.GIS_LOCK()
set.GIS_LOCK(pid)
unset.GIS_LOCK()
unlink_.gislock()
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gisBase</td>
<td>The directory path to GRASS binaries and libraries</td>
</tr>
<tr>
<td>home</td>
<td>The directory in which to create the .gisrc file; defaults to $HOME on Unix systems and to USERPROFILE on Windows systems; can usually be set to tempdir()</td>
</tr>
<tr>
<td>SG</td>
<td>An optional SpatialGrid object to define the DEFAULT_WIND of the temporary location</td>
</tr>
<tr>
<td>gisDbase</td>
<td>if missing, tempdir() will be used; GRASS GISDBASE directory for the working session</td>
</tr>
<tr>
<td>location</td>
<td>if missing, basename(tempfile()) will be used; GRASS location directory for the working session</td>
</tr>
<tr>
<td>mapset</td>
<td>if missing, basename(tempfile()) will be used; GRASS mapset directory for the working session</td>
</tr>
<tr>
<td>override</td>
<td>default FALSE, set to TRUE if accidental trashing of GRASS .gisrc files and locations is not a problem</td>
</tr>
<tr>
<td>use_g_dirseps.exe</td>
<td>default TRUE; when TRUE appears to work for WinGRASS Native binaries, when FALSE for QGIS GRASS binaries; ignored on other platforms.</td>
</tr>
<tr>
<td>pid</td>
<td>default as.integer(round(runif(1, 1, 1000))), integer used to identify GIS_LOCK; the value here is arbitrary, but probably should be set correctly</td>
</tr>
</tbody>
</table>

Details

The function establishes an out-of-GRASS working environment providing GRASS commands with the environment variable support required, and may also provide a temporary location for use until the end of the running R session if the home argument is set to tempdir(), and the gisDbase argument is not given. Running gmeta shows where the location is, should it be desired to archive it before leaving R.

Value

The function runs gmeta before returning the current values of the running GRASS session that it provides.

Note

If any package command fails with a UTF-8 error from the XML package, try using setXMLencoding to work around the problem that GRASS modules declare –interface-description output as UTF-8 without ensuring that it is (French is of 6.4.0 RC5 latin1).

Examples

```r
## Not run:
initGRASS("/usr/bin/grass-6.4.4", home=tempdir())
initGRASS("C:/GRASS", home=tempdir())

## End(Not run)
```

Description

Read GRASS 6+ raster files from GRASS 6+ into R SpatialGridDataFrame objects, and write single columns of R SpatialGridDataFrame objects to GRASS 6+. `readRAST` and `writeRAST` use temporary binary files and `r.out.bin` and `r.in.bin` rather than the temporary ASCII files used in earlier implementations. The earlier versions may still be used in a transition period. The functions `readRAST` and `readRAST6` as well as `writeRAST` and `writeRAST6` are identical and the functions ending with ...6 are maintained only for backward compatibility and might be deprecated.

Usage

```r
readRAST(vname, cat=NULL, ignore.stderr = NULL, NODATA=NULL, plugin=NULL, mapset=NULL, useGDAL=NULL, close_OK=TRUE, drivername="GTiff", driverFileExt=NULL, return_SGDF=TRUE)
writeRAST(x, vname, zcol = 1, NODATA=NULL, ignore.stderr = NULL, useGDAL=NULL, overwrite=FALSE, flags=NULL, drivername="GTiff")
```

Arguments

- **vname**: A vector of GRASS 6.0 raster file names
- **cat**: default NULL; if not NULL, must be a logical vector matching vname, stating which (CELL) rasters to return as factor
- **ignore.stderr**: default NULL, taking the value set by `set.ignore.stderrOption`, can be set to TRUE to silence `system()` output to standard error; does not apply on Windows platforms
- **plugin**: default NULL does auto-detection, changes to FALSE if vname is longer than 1, and a sanity check will be run on raster and current region, and the function will revert to FALSE if mismatch is found; if TRUE, the plugin is available and the raster should be read in its original region and resolution; if the plugin is used, no further arguments other than mapset are respected
mapset default NULL, if plugin is TRUE, the mapset of the file to be imported will be autodetected; if not NULL and if plugin is TRUE, a character string overriding the autodetected mapset, otherwise ignored

useGDAL default NULL, taking the value set by set.useGDALOption; use r.out.gdal or plugin and readGDAL if autodetected or plugin=TRUE; or for writing writeGDAL, GTiff, and r.in.gdal, if FALSE using r.out.bin or r.in.bin

close_OK default TRUE - clean up possible open connections used for reading metadata; may be set to FALSE to avoid the side-effect of other user-opened connections being broken

drivername default "GTiff"; a valid GDAL writable driver name to define the file format for intermediate files

driverFileExt default NULL; otherwise string value of required driver file name extension

return_SGDF default TRUE returning a SpatialGridDataFrame object, if FALSE, return a list with a GridTopology object, a list of bands, and a proj4string; see example below

x A SpatialGridDataFrame object for export to GRASS as a raster layer

zcol Attribute column number or name

NODATA by default NULL, in which case it is set to one less than floor() of the data values, otherwise an integer NODATA value (required to be integer by GRASS r.out.bin)

overwrite default FALSE, if TRUE inserts "overwrite" into the value of the flags argument if not already there to allow existing GRASS rasters to be overwritten

flags default NULL, character vector, for example "overwrite"

Value

readRAST returns a SpatialGridDataFrame objects with an data.frame in the data slots, and with the projection argument set. Note that the projection argument set is the the GRASS rendering of proj4, and will differ from the WKT/ESRI rendering returned by readVECT in form but not meaning. They are exchangeable but not textually identical, usually with the +ellps= term replaced by ellipsoid parameters verbatim. If return_SGDF is FALSE, a list with a GridTopology object, a list of bands, and a proj4string is returned, with an S3 class attribute of "gridList".

set.ignore.stderrOption(ois)
Description

readVECT moves one GRASS 6+ vector object file with attribute data through a temporary shapefile to a Spatial*DataFrame object of type determined by the GRASS 6+ vector object; writeVECT moves a Spatial*DataFrame object through a temporary shapefile to a GRASS vector object file. vect2neigh returns neighbour pairs with shared boundary length as described by Markus Neteler, in https://stat.ethz.ch/pipermail/r-sig-geo/2005-October/000616.html. cygwin_clean_temp can be called to try to clean the GRASS mapset-specific temporary directory under cygwin. The functions readVECT and readVECT6 as well as writeVECT and writeVECT6 are identical and the functions ending with ...6 are maintained only for backward compatibility and might be deprecated.

Usage

readVECT(vname, layer, type=NULL, plugin=NULL, remove.duplicates = TRUE, ignore.stderr = NULL, with_prj=TRUE, with_c=FALSE, mapset=NULL, pointDropZ=FALSE, driver="ESRI Shapefile")
writeVECT(SDF, vname, v.in.ogr_flags=NULL, ignore.stderr = NULL, driver="ESRI Shapefile")
vInfo(vname, layer, ignore.stderr = NULL)
vColumns(vname, layer, ignore.stderr = NULL)
vDataCount(vname, layer, ignore.stderr = NULL)
vect2neigh(vname, ID=NULL, ignore.stderr = NULL, remove=True, vname2=NULL, units="k")

Arguments

vname A GRASS 6+ vector file name
layer a layer name (integer in GRASS 6, string in GRASS 7); if missing set to default of 1
type override type detection when multiple types are non-zero, passed to v.out.ogr
plugin default NULL for auto-detection, may be set to FALSE to avoid or TRUE if the plugin is known to be available; if the plugin is used, no further arguments other than mapset are respected
remove.duplicates In line and area vector objects, multiple geometrical features may be associated with a single cat number, leading to duplication of data rows; this argument attempts to combine the geometrical features so that they match a single data row
ignore.stderr default NULL, taking the value set by set.ignore.stderrOption, can be set to TRUE to silence system() output to standard error; does not apply on Windows platforms
with_prj default TRUE, write ESRI-style PRJ file for transferred data
with_c
default TRUE in GRASS 6, FALSE in GRASS 7; if TRUE in GRASS 6 or FALSE in GRASS 7, export features with category (labeled) only; if not default, all features are exported, including GRASS “islands” which are probably spurious exterior rings filling holes.

mapset
if plugin is TRUE, the mapset of the file to be imported may be changed from the current mapset by passing a character string

pointDropZ
default FALSE, if TRUE, discard third coordinates for point geometries; third coordinates are always discarded for line and polygon geometries

driver
default "ESRI Shapefile"; a valid OGR writable driver name to define the file format for intermediate files, one of c("GML", "SQLite"), c("ESRI Shapefile", "MapInfo_File")

SDF
A Spatial*DataFrame to be moved to GRASS6 as a vector object, for SpatialPointsDataFrame, SpatialLinesDataFrame, and SpatialPolygonsDataFrame objects

v.in.ogr_flags
Character vector containing additional optional flags and/or options for v.in.ogr, particularly "o" and "overwrite"

ID
A valid DB column name for unique identifiers (optional)

remove
default TRUE, remove copied vectors created in vect2neigh

vname2
If on a previous run, remove was FALSE, the name of the temporary vector may be given to circumvent its generation

units
default "k"; see GRASS v.to.db manual page for alternatives

Value

readVECT imports a GRASS6+ vector object into a Spatial*DataFrame object with the type determined by the type of the GRASS6 vector object; vect2neigh returns a data frame object with left and right neighbours and boundary lengths, also given class GRASSNeigh and spatial.neighbour (as used in spdep). The incantation to retrieve the neighbours list is sn2listw(vect2neigh())$neighbours, and to retrieve the boundary lengths: sn2listw(vect2neigh())$weights. The GRASSNeigh object has two other useful attributes: external is a vector giving the length of shared boundary between each polygon and the external area, and total giving each polygon’s total boundary length.

Note

Please note that the OGR drivers used may not handle missing data gracefully. From rgdal release 0.5-27, missing values are taken as unset OGR field values. If the OGR driver encodes them in this way, NAs will be moved across the interface correctly from R to GRASS, and from GRASS to R using the OGR GRASS vector plugin. Work is continuing to correct v.out.ogr so that it emits unset fields, which affects users with no OGR GRASS plugin for the present. Thanks to Dylan Beaudette for helping with missing data handling.

Please also note that, on Windows and Cygwin systems, the temporary shapefiles are not removed by the interface functions, nor can GRASS remove them on termination - they must for the time being be removed manually. Windows believes that the GDAL/OGR library is still using them.
